—Wodon describes a simple technic for performing low cesarean section extraperitoneally. The first step is a median subumbilical incision of the skin and fascia along the white line. The rectus muscles are separated, exposing an oval zone of parietal peritoneum with the bladder at the bottom. A transverse incision of the parietal peritoneum is made (as long as possible) in the immediate vicinity of the bladder. The bladder is pushed downward behind the pubis by an assistant. A transverse incision of the uterine peritoneum is made in the immediate vicinity of the bladder and is prolonged to the right and left broad ligaments. The uterine peritoneum is detached as high as possible from the entire anterior face of the inferior segment. The flap of the parietal peritoneum and the upper flap of the uterine peritoneum are immediately sutured. The free peritoneum on each side of the uterus is closed with a purse string suture. A compress is placed over the peritoneal suture, leaving only the lower segment of the uterus and the bladder uncovered. The bladder is separated from the lower segment of the uterus and is held down by the assistant while the surgeon begins a transverse incision of the uterine muscle enlarging it with scissors. The edges of the uterine gap are provisionally closed with Duval's forceps. Five units of solution of pituitary is injected in the uterine muscle, delivery is spontaneous or obtained by Credé's method. The uterine wound is sutured with individual catgut sutures and then with a whip-stitch. The bladder is placed in front of the inferior segment and is fixed close to the peritoneal suture by individual catgut sutures. The rectus muscles and the aponeurosis are sutured, a drain of silkworm-gut being placed under the aponeurosis in the lower angle of the wound. Skin suture is done with silkworm-gut or clips. If necessary after the uterine wound has been closed, a large gauze drain may be pushed down behind the bladder till it is felt through the vaginal wall and after closure of the abdominal incision an anterior colpotomy is performed guided by the retrovesical tampon. The transverse incision of the inferior segment employed in this operation does not require much detachment of the bladder and does not endanger any vein of the latero uterine plexus. Permanent exclusion of the abdominal cavity by sutures is preferable to temporary exclusion.

*Paravertebral and Suprascapular Thoracoplasty F. Ody—p. 318

Paravertebral and Suprascapular Thoracoplasty—Ody describes the technic of high partial thoracoplasty by the paravertebral and suprascapular route. Usually he performs this operation as the second intervention in a total thoracoplasty in certain fibrocaceous tuberculous and acute cases in which pneumothorax alone is insufficient. The chief advantage of performing the operation in two stages is that it permits resection of the first rib, without which the compression of the diseased lung and particularly the apex remains incomplete. The author usually resects all ribs from the eleventh to the fifth inclusive during the first intervention and completes the thoracoplasty in from eight to fifteen days later. The first step of the second intervention consists in making an incision, starting slightly behind the acromioclavicular articulation, running parallel with the upper edge of the scapula about two fingerbreadths above it and turning at the medial angle of the scapula to descend paravertebral half way between the spinal edge of the scapula

and the spinous processes. It curves slightly away from the spine as it approaches its end about three fingerbreadths below the tip of the scapula. The incision crosses the trapezius muscle, but in its uppermost part it is parallel to the muscle fibers, which are only dissociated not divided. Keeping the innervation intact is more important than keeping all the muscles intact. The spinal nerve, which appears immediately below the trapezius toward the middle of the suprascapular incision, and the adjacent suprascapular and posteroscaphular venous plexus are preserved. The rhomboid muscle is divided close to its spinal insertion to avoid the rhomboid nerve. It is essential to avoid cutting the levator scapulae, which is the key to the subtrapezian region. The levator scapulae is drawn aside with a retractor and with it the spinal nerve, the rhomboid nerve the posterior scapular artery, the anastomosis of the posterior scapular and the suprascapular artery, and the perilevator venous plexus. The first rib appears between the insertions of the posterior scalenus muscle and those of the first external intercostal. After denudation and resection of the ribs, the rhomboid and trapezius are sutured in separate planes and the incision is closed.

Central Chondrosarcoma of Metaphyses—Guleke points out that central chondrosarcomas of tubular bones near the joint can be readily recognized in a roentgenogram. They represent a distinct group differing from peripheral sarcoma by their relative benignity as pointed out by Kienboeck, Grefenstein, Phemister and others. The author reports three cases whose histories and course bear a great similarity to one another. Occurrence of a fracture in two cases had no effect on the rate of growth. The roentgenogram is so characteristic as to enable one to differentiate this tumor from other sarcomas. It differs from the central sarcoma by a characteristic honeycombed appearance due to a great number of areas of lesser density evenly distributed throughout the tumor. The differential diagnosis from osteitis fibrosa is more difficult but is possible if the following points are observed: 1. Bone enlargement in chondrosarcoma takes place more regularly in all directions. 2. The tumor contains a great number of small, equal areas of lesser density, which are less transparent than similar areas in osteitis fibrosa because they are filled with cartilaginous tissue. 3. The outline of the tumor is less distinct than in osteitis fibrosa. 4. A radiating appearance is observable in some parts of the tumor as well as cortical thickening in other parts. 5. The tumor may break through into the surrounding soft tissue. Biopsy is indicated in doubtful cases. The course of the disease is long and relatively benign, a fact pointed out by Kienboeck, Phemister and Grefenstein. In the author's cases, symptoms existed seven, eight and fourteen years prior to the diagnosis. Phemister's patients were alive ten, nine and nine and one-half years after the excision of the tumor. Kienboeck's patient lived twenty years after resection of the chondrosarcoma of a vertebra. Because metastases are surprisingly late in appearance, an operation may still be undertaken at a stage at which it would be deemed hopeless in a central sarcoma. The author considers it unnecessary to perform an exarticulation or amputation of the limb. Resection of the tumor is sufficient, but removal of the joint capsule is important in prevention of recurrence.

Bleeding Nipple—According to Wolpers, a bleeding nipple suggests pathologic or physiologic changes in the breast. It makes its appearance as a single, continued, intermittent or cyclic discharge. The symptom may be observed in the so-called precancerous states, in cancer in benign pathologic processes of the breast and in many histologically obscure benign processes with or without tumor formation. At the University of Leipzig surgical clinic there were five instances of bleeding from a nipple among 414 cases of carcinoma of the breast, an incidence of 1 per cent. No instance was observed in which the bleeding nipple proved to be a precancerous condition. Klose's rule, therefore, that every bleeding breast should be submitted to a radical amputation with dissection of the axillary lymph nodes appears to the author too dogmatic. In Payr's clinic, bleeding alone is not considered an indication for radical intervention. A difficult problem is presented by cases in which no palpable tumor is demonstrable. Such cases were known occasionally to pass on to malignancy though more frequently they cleared up. A bleeding nipple in a man is much more likely to be associated with malignancy and therefore constitutes a definite indication for a radical operation.

Diseases of Pancreas—Rona and his school have in recent years demonstrated the presence of an atoxyl-fast pancreatic lipase in the blood serum. Schmitt presents his results with the stalagmometric method of Rona and Michaelis for determination of the pancreatic atoxyl-fast lipase in the blood serum in acute and chronic diseases of the pancreas. He found that the lipase was increased considerably above the normal in every one of the ten investigated cases of acute hemorrhagic pancreatitis. The degree of severity of the process, however, could not be estimated from these observations. The lipase increase persisted longer than the corresponding diastase increase in the urine. An increase in the blood lipase was likewise found in 90 per cent of thirty cases of chronic pancreatitis. In gallstone disease the commonest cause of both acute and chronic pancreatitis, the lipase was found frequently above normal though it never approached the values seen in acute necrosis of the pancreas. The lipase content of the blood was frequently found increased in ulcer of the stomach or duodenum, in all probability as the result of pancreatic involvement. No increase was noted in ileus, perforation of gastric ulcer or peritonitis conditions frequently confused with acute hemorrhagic pancreatitis. The lipase was not increased in tuberculous or chronic suppurative processes. On the contrary, it was found not infrequently diminished. The lipase was increased in hyperthyroidism and in primary and secondary anemias and there was even a greater increase in carcinoma. The author concludes that the determination of pancreatic lipase in the blood serum is of considerable value for the diagnosis of acute hemorrhagic pancreatitis and that in many respects it is superior to the determination of diastase in the urine.

Recurrence of Inguinal Hernia After Operation.—Birkenfeld discusses the role of operation and its complications and the role of the original factors responsible for the formation of hernia in the question of postoperative recurrence. In an analysis of 468 cases of hernia he calls attention to the existence of two sets of factors responsible for the formation of a hernia in the first instance: (1) external causes such as occupation, sport or trauma, and (2) internal predisposing factors. The latter have to do with a general weakness of the connective tissues suggested in some of the cases by the simultaneous existence of hemorrhoids, varices, enteroptosis, prolapse of the female genitalia or flatfoot. The existence of a familial congenital predisposition to hernia is of even greater importance. The author found a congenital predisposition in 225 of 468 cases, or 48 per cent. The predisposition in men was four times as great as in women. External factors, such as occupation or sport, had little influence on the incidence as seen from the fact that congenital hernia in infants and in children showed an even greater preponderance in males, namely, a ratio of 5.8:1. It is obvious that the operation removes the hernia and not the predisposing causes. The author attaches little importance either to the operation or to its complications, such as wound infection or bronchitis. The role of congenital predisposition is evident from the fact that, in a follow-up study, a recurrence was observed in 50 per cent of the cases presenting a history of a congenital predisposition. All patients with two

recurrences had a congenital tendency. The author recommends for such cases avoidance of unusual body exertions after operations for the cure of hernia so as to mitigate at least the external causative factors.

Carcinoma in Burn Scar and Symmetrical Carcinoma of Extremities—Arndt reports a case of bilateral symmetrical carcinoma of the legs developing in scars from a burn. He presents statistics to show that scars resulting from burns are particularly prone to develop carcinoma. Among 20,544 cases of cancer in Heinemann's statistics, there were 207, or 1 per cent, cancers of the extremities. In 10,864 cases of cancer reported by Gurlt, there were 168, or 1.5 per cent, carcinomas of the extremities. In von Brunn's statistics of 368 cases of cancer of the extremities, 33, or 9 per cent, developed in scars from a burn. It appears, therefore, that 9 per cent of cancers of the extremities are caused by burns or that 0.1 per cent of all cancers are caused by scars due to burns. Of the latter three fourths are found in the lower extremities. The carcinoma may develop immediately on scar formation or after an interval of many years. The growth may assume the form of an ulcer or of a tumor. The incidence in men is three times as great as in women. The average age was 47 years. Carcinomas developing after an interval of many years occur in the majority of cases (more than 50 per cent) in burns sustained in earliest youth (first decade of life). Carcinomas with a short interval belong to a more advanced age, the average being 48 years. Thus it appears that the burn acts as a predisposing rather than causative factor. Scars on extremities are more liable to cancer because of greater exposure to traumatism. Histologically the tumor is typically one made up of flat cornified epithelium. Like all skin carcinomas, it is the least malignant of all carcinomas and because of the possibility of radical removal offers a fair prognosis. The literature contains nine cases of symmetrical carcinoma of the extremities. The author's case is unique in that it describes for the first time a symmetrical bilateral carcinoma of the extremities developing in scars from a burn.

Hyperthermia Produced by Physical Methods—Walinski produces hyperthermia by injection of hypertonic solutions of sodium chloride and by hot baths with subsequent packing so as to retain the hyperthermia. He first tried this form of fever treatment five years ago. The intravenous injection of 10 cc of a 20 per cent solution of sodium chloride is given in order to reduce the sweat secretion and to stimulate the heart action. By reducing the sweat secretion it becomes possible to retain the increased temperature for longer periods. Other advantages of the sodium chloride injection are that it frequently facilitates a more rapid increase in the body tem-

perature during the bath and that the hyperthermia is usually more readily tolerated. About five minutes after the injection, the patient is given a bath with a temperature of from 37.5 to 38 C (99.5 to 100.4 F). After from twelve to thirty minutes, this temperature is increased to from 41 to 42 C (105.8 to 107.6 F). After the desired temperature has been reached, the patient is wrapped in one flannel and five wool blankets. The number and the duration of the pyrexia treatments depend on the disorder for which the patient is treated. The first treatment should, as a rule, not last longer than three hours, and the temperature should not exceed 39.5 C (103.1 F). Later the body temperature may be increased to from 41 to 41.5 C (105.8 to 106.7 F), and the treatments may last from five to seven hours. In the patients treated by the author the number of treatments varied between twelve and twenty and they were generally given every other day. In patients with dementia paralytica, the pyrexia treatments were followed by or combined with antisyphilitic therapy in the form of injections of bismuth compounds and neosarsphenamine. Tests revealed that during the physical hyperthermia there is a retention of sodium chloride and also an increase in the protein metabolism. Blood sugar content and alkali reserve decrease during the first stage of hyperthermia but increase again in the later stages, and a leukocytosis develops. The treatment was more or less effective in *tabes dorsalis*, cerebrospinal syphilis, dementia paralytica, multiple sclerosis, postencephalitis parkinsonism, myelitis polyneuritis, sciatica, chronic arthritis, pyelitis, bronchial asthma and inflammatory disorders of the adnexa. However in amyotrophic lateral sclerosis in all but one case of gonorrhea, in herpes zoster, and in psoriasis and nephritis the treatment was ineffective. Severe complications were never observed and none of the 353 patients died as the result of the treatment, whereas in therapeutic malaria the fatalities reach from 8 to 14 per cent. The author emphasizes that, compared to other forms of fever therapy, physical hyperthermia has the advantage that the dosage is more readily controlled and that it involves no danger whatever. The only contraindications to the treatment are severe cardiac and renal disorders. Patients with hypertension tolerated high temperatures comparatively well.

Oblongata Crises in Tabes Dorsalis—Strauss relates the clinical history of a patient, aged 38, who had the typical symptoms of *tabes dorsalis*, particularly, frequent attacks of gastric crises and of crisis-like attacks of lancinating pains, and who had twice attacks of respiratory paralysis with inspiratory stridor. In a review of the literature the author found records of twenty-one other cases of respiratory paralysis in *tabes dorsalis*. In many of these cases the attack developed shortly after administration of an alkaloid, but in some, and also in the reported case, no medication of this type had preceded, and from this the author concludes that respiratory paralysis may develop in patients with *tabes dorsalis* without any exotoxic influence. The reported case is noteworthy because in addition to the central respiratory paralysis, there developed still another inhibition of the respiration a severe inspiratory stridor, which was counteracted by intubation. The author thinks that this concurrence of respiratory paralysis and paroxysmal disturbance of the laryngeal innervation can be explained only by a common point of origin of the two conditions in the medulla oblongata, where the respiratory center and the motor nuclei for the laryngeal innervation are close together. Moreover, the loss of consciousness could likewise be explained by a functional disturbance in this region and therefore the author assumes a crisis-like disturbance in the oblongata. For the treatment of such conditions he advises the use of artificial respiration, administration of a lobelia preparation and intubation.

Obstetric Significance of Varicosis—Naujoks thinks that genital varicosis has not been given sufficient consideration as a frequent cause of severe complications in pregnancy. The chief danger of genital varicosis lies in hemorrhage. This may occur during pregnancy, at delivery or post partum. Varices discharging externally may be located in the vulva, vagina or perito, where they can usually be reached and blocked, or higher up in the cervix and the uterine wall, where they usually necessitate emptying of the uterus and laparotomy. Varices discharging internally may be located in the outer layers of the uterine wall close to the peritoneum and discharge into the peritoneal cavity or they may lead to hematomas in the labia, paracolpium or broad ligaments. Varicosis may be mistaken for placenta praevia, premature detachment of the placenta laceration of the cervix, rupture of the uterus or acute cardiac weakness. In case of severe hemorrhage toward the end of pregnancy attributed to placenta praevia the author advises a thorough examination of the vulva and lower end of the vagina for sources of hemorrhage before undertaking a surgical intervention. Sometimes diagnosis is impossible, in a case in which no varices were seen, cesarean section showed a normal placenta but severe varicosis of the cervix and anterior wall of the uterus. In another case, placenta praevia and varicosis occurred together. In patients with severe varicose hemorrhage, a repetition during future pregnancies should be guarded against. Genital varicosis may cause severe difficulties post partum, an episiotomy or a slight laceration may cause profuse and fatal hemorrhage. If the source of hemorrhage is in the vulva or near it deep acupression above and below are usually effective, if it is higher up it is best to apply large blunt clamps to the cervical wall and to any visible varicose plexus. If these measures fail, tamponade of the uterus, cervix or vagina with a nonabsorbent material is absolutely indicated. Varices discharging into the peritoneal cavity require laparotomy. Postpartum hematomas, if not visible should be suspected in case of tension, deep pain or unexplained anemia, careful palpation, especially from the rectum, should be undertaken. Treatment must be conservative; incision is indicated only if resorption does not occur within many weeks and there is much discomfort. The prognosis of varicose hemorrhages is difficult because it usually occurs in women of low resistance, especially sensitive to loss of blood.

Treatment of Arthritides with Roentgen Irradiation.—Ercklentz reports favorable results with high voltage roentgen therapy in secondary chronic arthritis, chronic gonorrheal and syphilitic arthritis, endocrine chronic periartthritis and arthritis deformans. He thinks that the roentgen rays have a favorable action on disturbances of the capillary mechanism of the joint, which in his opinion are at the basis of arthritis, and that they alleviate the nutritional disturbances of the diseased joint. This explains the change from an opaque, spotted atrophic appearance of the bony structure to normal structure, which has been pointed out by some observers as an effect of roentgen therapy. Roentgen irradiation in arthritides thus does more than alleviate pain and increase mobility and its use is indicated in all forms of chronic arthritis except in those with severe osseous changes and ankylosis, and in acute polyarthritis. It can do little to alleviate the osseous and cartilaginous changes in arthritis deformans, but it often results in good mobility of joints with severe anatomic changes. The roentgen rays effect a resorption of infiltrations and inflammatory exudates of the capsular ligament, which often cause severe pain, and by removing the cause of the pain remove one of the chief impediments to motion.

Raw and Cooked Food—Bischoff conducted experiments with rats to test the statement of Friedberger and Seidenberg that, in rats fed exclusively on peas, an increase in the duration of cooking of the peas is paralleled by a progressive decrease in the duration of life, and that, with a one-sided nourishment such as green peas, it is possible to keep the animals alive for a longer period only by the use of raw food but not by use of overcooked food. Determinations of the amount of food necessary to bring about an increase of 1 Gm. in body weight were included in the author's experiments and showed a pronounced

inferiority of nourishment with raw peas, while it seemed to make little difference whether the cooked peas were fed after one or three hours of cooking. His experiments indicate that a diet of raw food is not superior to a diet of cooked food. The development as well as the duration of life of the rats fed on raw peas was inferior to that of the animals fed on cooked peas.

Constitutional Thrombopathy—Von Willebrand and Jürgens describe a hemorrhagic diathesis, which they designate as 'constitutional thrombopathy'. One of the authors observed this diathesis several years ago in a girl aged 4. The child had extensive hemorrhages in the skin and in the mucous membranes and almost uncontrollable hemorrhages from the nose and the gums. Examination of the blood revealed thrombocytes of normal number and shape, normal coagulation and good retraction, but considerably prolonged bleeding time. More extensive investigations showed that this disorder was familial and hereditary. In three families that were studied, numerous members showed signs of this hemorrhagic diathesis, which could be traced back four generations. Both sexes were affected, but women somewhat more frequently and more severely than men. The most frequent form of hemorrhage in this condition is nosebleed to which nearly all these patients were subject at some time or other in their life, generally during childhood or puberty but occasionally during the menopause. Hemorrhages from the gums are another characteristic symptom and often give the impression of a scorbutic condition. The prolonged hemorrhages after slight injuries resemble greatly those of hemophilia. However, the blood picture, particularly the number of thrombocytes is normal. The morphology of the platelets is largely normal but the authors noted that there were more large ones than is normally the case. Moreover in spite of the normal number of platelets the thrombosis time (measured in the capillary thrombometer according to Morawitz and Jürgens) was enormously prolonged. In the case of the little girl it was more than ten times the normal length. The authors consider this deficient thrombus formation and changes in the blood fluid the essential factors of constitutional thrombopathy. The coagulation time of the blood is entirely normal, and this factor puts the discussed hemorrhagic diathesis in direct contrast with hemophilia. It differs from essential thrombopenia in that the number of platelets is not reduced. In Glanzmann's thrombasthenia, the bleeding time is normal pathologic forms of platelets are regularly found and retraction of the blood clot is abolished, which proves that it is a disturbance of the last phase of the coagulation process. The described constitutional thrombopathy, however, is essentially a functional disturbance of the platelet apparatus. The authors consider blood transfusion the most effective treatment of this form of hemorrhagic diathesis.

Pseudotuberculosis—By the term pseudotuberculosis Neugebauer means a specific inflammation, usually accompanied by nodule formation in the liver and occasionally in other organs, and caused by *Bacterium pseudotuberculosis-rodentium* Pfeiffer. The disease is well known in animal pathology but the author found only eight human cases reported in the literature. He reports in detail the results of postmortem pathologic and bacteriologic examinations in a case diagnosed at necropsy. In a man, aged 45, reported by his physician as having diabetes mellitus an undiagnosed illness of three weeks' duration, accompanied by fever, resulted in death. At necropsy a specific pathologic process with nodule formation was found in the liver, together with a general septicemic condition of the whole organism. Cultivation of *Bacterium pseudotuberculosis-rodentium* Pfeiffer from the liver and the spleen confirmed the diagnosis of pseudotuberculosis indicated by the gross and microscopic anatomic examinations. Inoculation with pure cultures of this organism produced identical changes in the livers of guinea pigs. *Bacterium pseudotuberculosis* was recovered in pure culture from the organs and blood of the test animals. Suspensions of *Bacterium pseudotuberculosis* isolated from the patient were agglutinated by his serum in 1:2,000 dilution.

So-Called Weak Stomach—Kraupl states that the gastrointestinal disturbances, ranging from transitory stomachache, heartburn, postprandial vomiting or diarrhea to more severe disturbances experienced by many persons periodically or permanently and considered as manifestations of a so called weak stomach, are due to a disproportion between the functional capacity of the digestive tract and the dietetic demands made on it. One factor of this disproportion is an inadequate digestive function resulting from constitutional inferiority of the digestive tract or, more often, from acquired disturbances of the digestive function, such as infectious-toxic disturbances, anatomic changes, adhesions and surgical interventions, sympathetic or endocrine disturbances, psychic disturbances, constipation, reflex changes in disease of the gallbladder and pancreas, or cardiovascular disease. The other factor is an incorrect diet, that is, one not suited in quantity or quality to the functional capacity of the digestive tract. The production of the whole series of symptoms of "weak" stomach up to ulcer formation could often be avoided if the diet were made to conform permanently to the capacity of the digestive function. Therapy should aim at increasing the functional capacity by alleviating the acquired disturbances (often possible in cardiovascular disease, constipation and psychic disturbances), and at reducing the demands on the digestive function by administering only foods suited to the patients' digestive capacity.

Pallida Antigen Reaction—From a comparison of the pallida antigen reaction with the Wassermann reaction and the Meimcke clarification reaction Vohwinkel concludes that the pallida antigen reaction is a distinct improvement on the original Wassermann reaction and is especially superior to it in the examination of cerebrospinal fluid. The pallida antigen reaction is a complement fixation test for syphilis, performed exactly like the Wassermann reaction except that, in place of the usual antigen an antigen of cultures of *Spirochaeta pallida* in saline solution containing 0.3 per cent of phenol is used. This phenolized spirochetal antigen was introduced by Gaetgens a few years ago. Among 2,246 serums tested, 1,819 were negative with the Wassermann, Meimcke and pallida reaction. Among 284 serums from clinically and anamnestic certain cases of syphilis, 46.4 per cent were not detected by the Wassermann reaction, 8 per cent were not detected by the Meimcke reaction and 11.6 per cent were not detected by the pallida reaction. The pallida reaction detected 84 per cent of the syphilitic cases that were not detected by either the Wassermann or the Meimcke reaction. Although no definite conclusion concerning the specificity of the pallida reaction (tested chiefly with respect to malaria) could be made, it appeared to be equal to that of the Meimcke reaction but slightly inferior to that of the Wassermann reaction. In examinations of cerebrospinal fluid the pallida

reaction detected eight among seventeen positive cases that were not detected by the Wassermann reaction, and in three cases it gave a stronger positive reaction.

Angina Pectoris Diaphragmatica.—Hofbauer calls attention to the contradictions in the numerous suggestions that have been made for the treatment of angina pectoris. He shows that these contradictions arise from the fact that neither the location nor the nature of the disorder is clearly understood. The pathogenesis of angina pectoris has been ascribed to changes in the coronary arteries, to myocardial changes and to aortic changes. However anatomic researches and animal experiments based on these theories did not clear the pathogenesis of angina pectoris. Careful observation of the clinical aspects of attacks of angina pectoris revealed that there are three different conditions that may lead to an attack: overfilling of the stomach and intestine, the influence of cold and overexertion. The common factor of these three conditions is their influence on the respiratory mechanism on the statics and kinetics of the diaphragm. This becomes the more understandable by the author's observation that angina pectoris concurs with changes in the position and the motility of the diaphragm. He calls attention to the anginous conditions that occur following operative treatment of pleural empyema, in which it is always the change in position of the patient that causes the attack, while return to the old position, as a rule, counteracts it. Roentgenoscopy reveals always in these cases a certain change in the position of the diaphragm and an inhibition of its motility, for it adheres to the lateral thoracic wall and is in an abnormally high position. The "respiratory blockage" and the pains in the chest are thus easily understandable. However, these symptoms develop not only in case of pleural adhesions but also when the diaphragm is forced upward as the result of abdominal pressure. In this connection the author calls attention to reports by other observers, to M Herz's "phrenocardia" to Römhild's "gastrocardiac syndrome," to von Bergmann's "epiphrenal syndrome" (THE JOURNAL, July 2, 1932, p. 89) and to Sauerbruch's "hiatus hernia" (THE JOURNAL, Nov. 12, 1932, p. 1734). However, he warns against generalization of a casual connection between diaphragmatic hernia and angina pectoris, and he cites a case in which the anginous disorder did not develop until after the closure of a diaphragmatic hernia. Yet he accepts as generally true a connection between angina pectoris and diaphragmatic disturbances. In cases in which the diaphragm is free from organic disorder changes in the central circulatory apparatus (coronary arteries, aorta, myocardium) may produce a hyperesthesia of the diaphragm by means of a viscerosensory reflex, the hyperesthesia in turn producing a respiratory blockage and a painful contraction of the chest. The fact that the dysfunction brought on by organic changes has practically the same symptoms as that produced by reflex action is explained by the fact that in the two cases there is the same effect, namely, hyperesthesia of the diaphragm.

Ambulatory Pneumothorax Therapy.—On the basis of observations on 229 cases, Reichel and Biedermann consider ambulatory pneumothorax treatment possible, provided the patient is in good general condition and free from fever. How-

ever, at the beginning of the treatment the patient should be hospitalized for about ten days in order to have him under observation not only while the pneumothorax is induced but also during the first and second refilling. In case of fever or of other troubles, the period of hospitalization should be extended. The pneumothorax was unilateral in 208 and bilateral in 21 of the cases. In the latter the hospitalization was extended ten days of hospital treatment being given for each side. The ambulatory refilling was done either alternately on the two sides or simultaneously, depending on the conditions in each patient. The authors state that the results of the ambulatory pneumothorax treatment were satisfactory.

Shortening and Shifting of Sleeping Period.—Stöckmann observed on several students that a shortening of the sleeping period but at the same time a shifting so that it was completed before midnight had a favorable effect. Fatigue and nervousness disappeared and mental alertness increased. The reports indicate that the sleep generally lasted from 7 p. m. to 11 20 p. m. Up to the present, observations have been made on fifteen persons (adolescents and adults) all of whom found the sleeping period between 7 p. m. and 11 20 p. m. most suitable.

Abduction Splint Treatment in New Shoulder Injuries.—Mau deplors that periarthritides humeroscapularis is not yet recognized by many practitioners and states that incorrect treatment may result in an irreparable limitation of the movement of the shoulder, while a correct early treatment makes it possible to prevent such conditions of contraction. The main object is to bring the arm as soon as possible, into the abduction and external rotation position, and to secure immobilization for arm and shoulder by fixing the arm in this position by means of a special splint. The author describes and illustrates the splint and its application. The splint should not be removed until active lifting of the arm to the same extent as the healthy one becomes possible. This requires, as a rule, several weeks. If the splint is removed too early, the movement may become impaired again. In the first few days following the removal of the splint the patient should be carefully watched and, if necessary, the splint should be put on again. After the original pains have disappeared adjuvant measures, such as massage and application of heat, may be instituted while the arm is in the abducted position, but these measures are not the main indication and are not absolutely necessary. A sufficiently prolonged and uninterrupted abducted position and active movement as soon as this becomes necessary are the most important factors.

Endolumbar Administration of Acriflavine Hydrochloride.—Eigler and Geisler cite the clinical histories of three patients with meningitis showing that the endolumbar administration of acriflavine hydrochloride involves great danger. They do not deny that frequently the suppurative processes of the spinal cord are favorably influenced by this treatment, but this favorable influence does not compensate for the serious paralyses that they have observed. Two monkeys inoculated with meningitis and then treated with endolumbar administration of acriflavine hydrochloride likewise developed paralysis. On the basis of these experiences the authors warn against the endolumbar injection of this preparation in patients with meningitis. Moreover, postmortem examinations revealed that the acriflavine hydrochloride had advanced only to the base of the brain, which indicates that rhinogenic and otogenic meningitis cannot be influenced by the endolumbar administration. The authors think that, besides the surgical interventions, the frequent and copious evacuation of the lumbar canal promises the best therapeutic results in acute suppurative meningitis.

Anemia of Pregnancy Resembling Pernicious Anemia
—Pohl calls attention to the fact that in normal gravidity the development of a slight anemia can be observed. He thinks that the anemia is not merely simulated by a hydremia but is the result of an increased disintegration of the blood. If an impairment of the bone marrow existed before the beginning of the pregnancy, an anemia of a somewhat pernicious form may eventually develop in the course of the pregnancy. Impairment of the bone marrow may be caused by a rapid succession of pregnancies, by infectious diseases and by blood diseases (essential hypochromic anemia). It is possible that an anemia of pregnancy resembling pernicious anemia develops from a pregravidic essential hyperchromic anemia. A case history seems to indicate this. During the puerperal period, treatment with liver preparations hastens recovery from the anemia that resembles the pernicious form. Whether this therapy will also be effective during pregnancy has yet to be proved with the new preparations, however the results with fresh liver have been encouraging. If shortly after delivery, the woman's life becomes endangered, blood transfusion becomes necessary.

Anemia of Pregnancy Resembling Pernicious Anemia
—Batsweiler shows that anemia of pregnancy is probably a toxicosis of pregnancy, the morphologic blood picture of which frequently resembles that of pernicious anemia, whereas in other cases it resembles chlorosis. On this basis he differentiates two types: (1) the hyperchromic type which resembles pernicious anemia and in which the color index is over 1, and (2) the hypochromic type, which resembles chlorosis and has a color index of less than 1. The blood picture of both types shows pronounced oligocythemia, reduction of the hemoglobin and occurrence of young forms and of degenerative manifestations. The other symptoms resemble those of the toxicoses of pregnancy. The symptomatology differs from pernicious anemia in the following points: 1. The bilirubin content of the serum is normal or only slightly increased. 2. Urobilinogen is present in the urine rarely or not at all. 3. The gastric secretion is normal; achlorhydria occurs rarely and if it does, it disappears again during the process of recovery. 4. Following delivery and the puerperal period, recovery is possible. 5. There is no relapse outside of the gestation period, and relapses are rare during this period. From the therapeutic standpoint it is important that a considerable improvement can be effected during pregnancy with the aid of liver and stomach preparations, making it possible to bring the pregnancy to term. In the treatment of the hypochromic type, iron preparations are helpful in compensating for the iron deficiency. The prognosis of anemia of pregnancy is favorable, provided it is recognized and properly treated during the early stage. Interruption of pregnancy is not necessary, for with the aid of liver, stomach and iron treatments, and with blood transfusion, it has been possible to reduce the formerly high mortality to 15 per cent and to produce mature and viable children.

Prospects of Conception Following Salpingostomy
—Dworzak and Hajek consider the operative opening of the uterine tubes that have been closed by inflammation an ineffective treatment of sterility. A study of the case histories of fifty-two women who underwent this operation revealed that fifty-one had not become pregnant, in spite of a sincere desire for children, and that in one woman the intervention had led to tubal pregnancy. On the basis of this observation, they

abandoned this treatment of sterility, and they are inclined to believe that unfavorable results and dangerous complications are more frequent in salpingostomy than is generally reported. They think that statistics on a larger material will have to prove whether it is justifiable to resort to salpingostomy in the treatment of sterility, or whether the failures and complications are more frequent than the favorable results.

Extra-Uterine Endometrioid Proliferations — Kleine points out that extra-uterine endometrioid heterotopias may lead to diagnostic mistakes, as shown by the following observations: 1. An endometriosis of the appendix that was accompanied by other extra-uterine endometrioid proliferations was diagnosed as chronic appendicitis. 2. An endometriosis of the right round ligament was treated for years as inguinal hernia. 3. Three cases of endometriosis in the posterior vaginal wall were thought to be of a carcinomatous nature. In one of these the endometriosis had developed following vaginal total extirpation of the uterus. 4. A nodule formation under the epidermis in a laparotomy scar following cesarean section was recognized as endometriosis during the histologic examination. 5. In a woman, aged 40, a constricting endometriosis of the vagina, located on the posterior wall in the middle of the vaginal tube, that is, unusually low, was considered for several years as probably of tuberculous character.

Contrast Mediums in Retrograde Pyelography — The many different contrast mediums that have been recommended for retrograde pyelography and the diversity of opinions about the value of the different substances induced Sartorius and Viethen to make a systematic study of their suitability. They reach the conclusion that the modern complex iodine compounds, such as iopax, insure a painless, safe and entirely nonirritant pyelography. For this reason they are at present accepted as the best contrast mediums for retrograde pyelography. The authors further show that a colloidal thorium dioxide preparation offers the same advantages as the complex iodine preparations, besides still giving a good roentgen shadow at a dilution of from 1:1 to 1:2, and therefore being much cheaper than the complex iodine compounds. Its disadvantage is its storage capacity in the renal region, which is not likely within the limits of permissible pressures of injection but is possible in certain disease conditions of the renal pelvis and of the renal tissues and may cause the erroneous diagnosis of renal concretions. In interpreting pyelograms that have been made with the thorium dioxide preparation, the possibility of the storage of renal extravasates should therefore always be considered.

***Treatment of Hypertrophy of Prostate** — Rabinowitsch discusses various diagnostic methods: (1) rectal palpation of the prostate and its surroundings, (2) determination of the residual urine, (3) cystoscopy, (4) roentgenologic demonstration of the urinary bladder and of the kidneys either by means of contrast filling or, in some cases, by means of pneumoradiography, (5) functional examination of the kidneys. The latter is done by means of the dye test, the water test, the concentration test, the urea tolerance test according to MacLean and eventually the determination of the urea and of the rest nitrogen in the blood. The author makes, as a rule, all

these tests because the partial functions of the kidney may be impaired in varying degrees. With the aid of the various tests, it is possible to obtain a clear picture of the condition of the prostate and of the urinary apparatus. The local examination should of course be preceded by a general examination in which the cardiac function and the blood pressure are given consideration, and the therapeutic procedure should be decided on the basis of the local and the general examinations. The author considers prostatectomy the method of choice. In patients who are in fair general condition, the entire procedure can be done at once, whereas two interventions are advisable in other patients. He describes suprapubic cystotomy which he performs under spinal anesthesia. The unburdening of the urinary apparatus produced by suprapubic cystotomy may have an unfavorable effect on the kidneys and also on the heart and the vascular system. For this reason the circulation should be given special attention in the interval between the cystotomy and the second part of the operation, namely the prostatectomy. Other factors that should be considered during this interval are strengthening of the organism, undisturbed discharge of the urine and treatment of cystitis, which exists almost invariably. The author performs prostatectomy likewise under spinal anesthesia. In patients in whom a suprapubic cystotomy cannot be done, he advises operation in three stages: first, vasectomy and introduction of the permanent catheter, later suprapubic cystotomy, and, finally, prostatectomy. Other treatments discussed are permanent catheterization, vesical fistula, and injection of a combination of a solution of pepsin and Pregl's solution of iodine—according to Payr's method. He advises treatment by permanent catheterization for old people who are not likely to tolerate a surgical intervention, for patients with serious cardiac and circulatory disturbances, and for patients in whom acute congestion of the prostate causes acute stasis of the urine. He recommends a permanent vesical fistula for patients in whom prostatectomy is contraindicated and in whom catheterization is impossible on account of urethral stricture. He has found intraprostatic injections of the pepsin and iodine solutions valuable in combination with catheterization.

Introduction of Gas into Renal Pelvis and Bladder.—Improvement of the asepis in suprapubic cystotomy, making cystotomy possible in certain cases and demonstration of ray permeable bodies in the bladder the ureter or the renal pelvis are, according to Spörl the main indications for gas inflation. Since a number of authors have advised against it on the basis of the danger of gas embolism the author decided to investigate whether this objection is justified. He concludes that, provided a correct technic is employed, introduction of gas into the renal pelvis and bladder is without danger. The precautionary measures consist (1) in the use of oxygen instead of air, (2) in the control of pressure by watching the backward dart of the plunger in fractional injection, (3) in limiting the amount of oxygen for filling the bladder to 150 cc., and (4) in avoiding gas inflation in patients in whom the circulation is impaired as the result of a weakened heart or of a pulmonary disorder.

Cerebral Gliomas.—Of 800 cases of brain tumor in which Heymann operated in the last ten years, 250 belonged to the glioma class. According to the author, the limitations of a classification of the type of Bailey-Cushing or of del Rio Hortega are that they are based solely on histologic grounds. The classification of P. Schwartz and the author's classification are based on the gross external features of the growth and are therefore of greater assistance to the clinician. The gliomas of the cerebellum are not included here, since they offer little difficulty as to localization, spread and clinical characteristics. Their

prognosis is likewise much better than that of cerebral gliomas. The author suggests a division into three distinct groups: (1) gliomas of the old, (2) polar gliomas and (3) gyrus gliomas. Gliomas of the old begin to manifest definite localizing symptoms in the fifth or sixth decade. A careful history usually reveals that years previously the patient had an epileptic seizure, a hemiplegia or psychic disturbances, and only exceptionally other than fleeting localizing symptoms. Prognosis is bad because the existence of the tumor is not recognized until some terminal event appears, the choked disk, headache and vomiting being usually overlooked until shortly before the end. The outlook for an operative intervention is hopeless in these cases and one should not yield to the temptation of doing a decompression operation since the resulting edema of both hemispheres can no longer be influenced. Tumors with mature neuroglia cells and rich in fibrous tissue offer a somewhat better prognosis. Such patients may survive for from several months to two years after the decompression operation. Polar gliomas are divided into those developing (a) in the occipital lobe, (b) in the temporal pole and (c) in the frontal pole. The polar gliomas are more amenable to surgical removal because they are more superficial. The prognosis, however, depends to a great extent on whether the tumor grew from the periphery inward or in the reverse order. Those of the frontal lobes give the more favorable prognosis. Resection of one frontal pole, especially of its basal portion, is well borne and offers a fair prognosis. The edema which sets in as a rule about two years later because of a recurrence, can be controlled by irradiation for months or years. The rest of the polar gliomas offer a bad prognosis. They are characterized by immature cells; they grow from within outward, and they give rise to symptoms surprisingly late. The temporal gliomas are practically all hopeless. The only exception is formed by a tumor located in the periphery of the lobe and confined to one convolution. The results after resection are at times quite striking. Recurrence, however, will not fail to take place from six to nine months later occasionally after a few weeks. The occipital gliomas offer the least difficulty to removal but are most malignant and recur more quickly than any other type of glioma. In the third group the author places tumors limited to a single convolution—gyrus gliomas. They are easily removed without much attending bleeding but recurrence will take place a few months after the operation. There are still other gliomas not included in the three groups described, such as those developing in the vicinity of the great nuclei and displaying a tendency to grow into the third ventricle, but these because of their location, are not operable. In the author's experience, irradiation not infrequently seemed to stimulate the growth of the tumor.

Extraction of Posterior Arm in Shoulder Presentation.—Since the literature reports no case in which drawing down the arm resulted in the delivery of a living child, Henkel calls attention to a case of his observation in which this proved possible. The woman in question had a normal pelvis but the fetus was large and was in the second postero-occipital position. When asphyxia developed and necessitated the rapid termination of the delivery, an attempt was made to engage the head with the aid of Naegele's forceps. This attempt failed, but Kielland's forceps accomplished the engagement though not the rotation of the head. Naegele's forceps were again employed and rotation of the head was easily obtained. Further extraction was again impeded because it was impossible to bring

the shoulder into the pelvis. For this reason the obstetrician introduced the left hand and drew down the right arm. After that the delivery offered no further difficulties, except that for a few days the right arm of the new-born infant showed a slight paresis. This case shows that extraction of the posterior arm is a manipulation that promises success in the difficult delivery even of the living child. In the reported case the pelvis was normal and the child oversized, but the same difficulties may develop with a child of normal size when the maternal pelvis is narrow, and the author thinks that lowering the arm should be tried in such cases.

Puerperal Pyemia—Zondek and Grunsfeld point out that neither serotherapy nor chemotherapy has accomplished the desired results in puerperal fever. Ligation of the veins can be employed only in rare cases. The main object in the treatment of septic infections is to increase the resistance of the organism. Since the oral application of strengthening substances is usually difficult because the patients lack appetite, the authors decided on the continuous intravenous infusion. As experience has proved that alcohol is helpful in septic infections, they administer a solution of dextrose and alcohol. On the first day, only a 5 per cent solution of dextrose is administered, and 0.5 per cent alcohol is added later, and the percentage gradually increased to 2. The drop infusion is arranged in such a manner that 100 cc is administered hourly. This quantity does not overtax the circulation, but after a few days it should be slightly reduced. The authors never experienced an embolism, and fifteen of the twenty women they treated in this manner recovered. Since all of the twenty cases were rather severe, they consider the mortality rate of 25 per cent not high. The solution of dextrose without alcohol but with cardiac stimulants instead has been found helpful after operations. Following great loss of blood, the authors prefer the solution of dextrose to physiologic solution of sodium chloride.

Intra-Uterine Interventions in Ectopic Pregnancy—The observations made by Magid and Pantschenko are summed up as follows: 1. Attempted abortion is not entirely rare in ectopic pregnancy. In the material studied it amounted to 7 per cent of the total number. 2. This mistake is generally made between the sixth and eighth weeks of pregnancy. For this reason it is advisable not to interrupt the pregnancy before this time. 3. The attempted abortion does not make the prognosis of ectopic pregnancy less favorable as far as operation and infection are concerned. This is owing to the fact that the intervention is usually done by a physician that is, under aseptic conditions. On the other hand, the uterine cavity does not contain material that could become infected (no ovum). 4. An attempted abortion masks the clinical aspects of ectopic pregnancy to such an extent that a correct early diagnosis becomes difficult. 5. The pregnant tube does not react to the intra-uterine intervention, and the rupture evidently is caused only by the growing trophoblast. 6. In order to differentiate an ectopic pregnancy from an incomplete abortion, it is advisable to resort to an exploratory scraping of the uterus. The presence of villi of the chorion has a certain significance, as it excludes an ectopic pregnancy. One should not forget that extra-uterine and intra-uterine pregnancies may concur.

Automammization by Mud Packs—Sdrawomysloff maintains that the close relations between the internal genitalia of women and their mammary glands have been proved clinically and experimentally. Besides secreting milk the mammary gland produces a hormone, the so called mammin, which is an

antagonist of one of the ovarian hormones, folliculin, which is related to some other hormones. It is well known that during the lactation period menstruation generally ceases and that, by the systematic administration of the mammary hormone, it is possible to produce cessation of the menses. Besides its inhibitory influence on the ovary, the hormone of the mammary gland also has a direct action on the uterine musculature. It increases labor pains and stimulates the contraction of the uterus following delivery. The manifold connections of the mammary glands with the internal female genitalia and the incomplete identity of the mammary hormone obtained from animals with that produced in women led to efforts to increase the formation of the hormone in the organism itself, that is, to automammization by means of mud packs on the breasts. This measure was employed in sixty-seven patients who had prolonged menstruation or metrorrhagia. The mammary gland was covered for from twelve to fifteen minutes with hot mud with a temperature of from 48 to 52 C (118.4 to 125.6 F). These mud packs of the breasts were usually combined with mud packs covering the body from the waist to the middle part of the thighs. After a certain number of treatments however, the packs were applied only to the mammary glands. The number of applications varied between six and twenty-four, the average being twelve. In fifty-seven cases (85 per cent) the treatment was more or less effective, and the authors recommend these mud packs for women with profuse menstruation, in many forms of fibromatosis and in cases of fibroma of the uterus.

Bibliotek for Læger, Copenhagen

- *Sugar Threshold and Kidney Function. C. T. Bjerring and P. Iversen.—p. 103
- Investigations on Kidney Function in Eclampsia and Related Disturbances of Pregnancy. A. Olsen.—p. 133

Sugar Threshold and Kidney Function—Bjerring and Iversen show that one threshold must be considered for the rising and another for the falling blood sugar curve. The sugar threshold is defined as that dextrose concentration in the blood (glomerulus filtrate) at which the dextrose concentration in the reabsorption fluid changes from higher than that of the blood to lower, or vice versa. They find that the reabsorption of dextrose decreases only relatively with the rising dextrose concentration in the blood. There is a linear correlation between the dextrose percentage in the reabsorbed fluid and the dextrose percentage in the blood (or filtrate). With the same blood sugar the kidneys reabsorb a thinner solution of dextrose when the blood sugar curve falls than when it rises. The dextrose percentage and the total elimination of dextrose in the urine depend on the height of the blood sugar and the concentration index. If the latter is kept constant the dextrose percentage in the urine can be made to run parallel with the dextrose percentage in the blood. In acidosis the tubuli are intoxicated and the effect is the reabsorption of a thin solution of dextrose. If the dextrose percentage in the reabsorbed fluid continues for a long period of time near the dextrose percentage in the blood the dextrose percentage of the urine corresponds to it. With increasing quantities of eliminated dextrose, the concentration index drops.

- Content of Quinine Resistant and Atoxyl Resistant Lipases in Blood from Normal Persons According to Rona. K. Germer.—p. 372

Whooping Cough—Brems finds that phenobarbital sodium in a 0.5 per cent solution usually in doses of 5 cc from three to six times daily, in most cases of whooping cough lessens the frequency and violence of the attacks and vomiting and the exhaustion. The reaction was good in about twenty out of sixty-four children and excellent in about thirty. The only unfavorable by-effects were an exanthem in seven cases and notable dulness in three. In several cases which showed signs of becoming grave the author gained the impression that the course of the disease was abortive after the administration of phenobarbital.

CONGENITAL HEART BLOCK

REVIEW AND REPORT OF THE SECOND CASE OF COMPLETE
HEART BLOCK STUDIED BY SERIAL SECTIONS
THROUGH THE CONDUCTION SYSTEM

WALLACE M. YATER, M.D.

JAMES A. LYON, M.D.

AND

PAUL E. McNABB, M.D.

Major M. C. U. S. Army

WASHINGTON, D. C.

In 1929 one of us¹ reviewed the literature on congenital heart block and reported the first case of complete heart block of congenital origin studied by serial sections through the conduction system. One other case of congenital heart block in which there was partial (2:1) block had been studied in this manner by Wilson and Grant.² The case to be reported is the second case of congenital, complete heart block studied histopathologically.

Congenital heart block is not common. In the review¹ in 1929 thirty cases were accepted from the literature as fulfilling certain diagnostic criteria. Many other cases were excluded because of insufficient proof either of their congenital origin or of the existence of heart block. The criteria of acceptance in certain instances may have been too rigorously applied. For instance Calandre's³ case was excluded because there was a possibility that the block was due to vagus nerve action and not to some cause existing at birth although the father of the patient who was first examined at the age of 21, stated that the pulse had always been slow. In this case examination of the heart was negative except for the bradycardia, and at times when the patient was in complete repose normal sinus rhythm was noted with the auricles beating at the same slow rate as the ventricles. As with many other uncommon conditions however it is probable that instances are noted from time to time which are not recorded. We are aware of a number of unreported clinical cases of congenital heart block seen by colleagues.

The criteria usually demanded for the diagnosis of congenital heart block are that the heart block must be proved by graphic methods in a relatively young individual, that the slow pulse must have been noted at a fairly early age and that there must not be a history of any infection which might cause the condition after

birth, such as diphtheria, rheumatic fever, chorea or congenital syphilis. The occurrence of syncope attacks at an early age is fairly good evidence of the existence of the heart block prior to the attacks. Such evidence was present in five of the accepted cases. The presence of signs of congenital heart disease, although not essential adds weight to the congenital origin of the condition, but one must remember that congenital heart lesions, such as patent interventricular septum, may be the seat of acquired endomyocarditis.

Since the review¹ in 1929 fourteen new cases from the literature, including the one here reported have been added to the list, making a total of forty-four accepted cases, which are given in the accompanying table. One of the new cases⁴ was missed in the previous search of the literature and another⁵ was reported while the paper was in press. Two cases previously reviewed and rejected because of lack of graphic proof of the existence of heart block are now accepted. These were of the two sisters reported by Aylward.⁶ Aitken⁷ has recently stated that complete heart block has since been demonstrated in these cases by electrocardiograms. It is now possible therefore to state positively that familial heart block occurs. Only one case reported as an instance of congenital heart block since the previous review has been rejected, this was case 1 of Aitken.⁷ The possibility of acquired rheumatic disease as the cause of the heart block could not be excluded, and the pulse rate at 9 months was 100.

The causes of congenital heart block are theoretically some developmental defect of the bundle of His and prenatal endomyocarditis or syphilis involving the bundle. Thus far, only the former cause has been demonstrated by necropsy. Developmental defects sufficient to cause heart block were present in the five hearts examined. In the case of Wilson and Grant,² in which incomplete heart block was present examination disclosed complete atresia of the root of the pulmonary artery with a large patent ductus arteriosus and a common ventricle with only the rudiment of an interventricular septum in the form of a rounded prominence in the posterior wall. Histologic study showed the auriculoventricular node to be well developed but the bundle was composed mainly of two strands with numerous branches embedded in dense fibrous tissue. In the case of Perotti,⁸ who was unable to obtain graphic records of the infant, who died three days after

birth, there was complete absence of the membranous portion of the interventricular septum. In the case of Yater,¹ a most unusual condition existed. There was complete transposition of viscera except for the ventricles of the heart, and the auriculoventricular node was completely separated from the bundle of His by the central fibrous body as demonstrated in serial sections. The case of Abbott and Moffatt⁹ was also one of unusual anomalies. There were a displaced left auricle, transposition of the great arterial trunks, double mitral ostium, cor batriatum trilobulare, right conus stenosis and congenital pulmonary arteriovenous aneurysm. In the case here reported there was a large defect in the interventricular septum with practically complete absence of the bundle of His.

In the cases that did not come to necropsy the diagnosis, made either by the original authors or by us from the description was patent interven-tricular septum in twenty-six. In two of these, pulmonary stenosis was also thought to exist and, in two others, patent ductus arteriosus. Pulmonary stenosis alone was diagnosed in one case, and communication between the aorta and pulmonary artery just above the aortic valve in another. In two cases cardiac murmurs that could not be interpreted were present. In six of the cases, clinical evidence of congenital heart disease other than the heart block or transient cyanosis was not found, and in three cases mention of the cardiac examination was not made.

In regard to the time of discovery of the slow pulse in the forty-four accepted cases bradycardia was noted during the first year of life in thirteen instances during the second year in five, between the second and tenth years in sixteen, and between the tenth and twentieth years in ten. In the first case of White, Eustis and Kerr¹⁰ the fetal heart beat was noted to be irregular eight hours before birth. In Yater's case¹ the diagnosis

of congenital heart block had been made by the obstetrician two weeks before birth because of the slow rate of the fetal heart beat.

In the forty-four cases the degree of auriculoventricular dissociation was complete in thirty-five partial in six, alternating between complete and incomplete in two and not determined in one. In the last case that of Perotti⁷ graphic records were not made but because of the bradycardia from birth and the cardiac defect found at necropsy it was considered to be one of heart block. In the case of Sprague and White⁴ partial heart block was present on the first examination but it was found to be complete eight months and again eighteen months later. The case of Smith¹¹ was unusual in that during forced expiration the heart block was replaced by sinus rhythm. Roentgenograms showed the position of the heart in forced expiration to be higher and more horizontal. Smith assumed that a few fibers of the bundle remained but that, except in the position of forced expiration there was an increased tension on them which prevented conduction. This was also one of the cases in which objective evidence of congenital heart disease was not found but the patient, a man, aged 20 had had syncopal attacks between the ages of 3 and 9 years.

The case of Bass¹² also was of special interest because at short intervals the electrocardiogram showed normal ventricular complexes preceded by normal P waves. The ability of the bundle of His to be activated at times by the auricular impulse indicates that in this case as in Smith's there was not a complete anatomic interruption of the bundle but that increased tension on it prevented its attenuated strands from conducting these impulses most of the time. If Calandre's² case were accepted, it might be explained on a similar basis.

Symptoms referable to the heart were present in very few of the cases. Cyanosis was entirely absent in

twenty-four, slight or occasional in fourteen, and marked in only six. Clubbing of the fingers was noted in only three. Dyspnea and other evidence of congestive failure were not noted in any of the cases. The degree of cardiac hypertrophy was designated as none

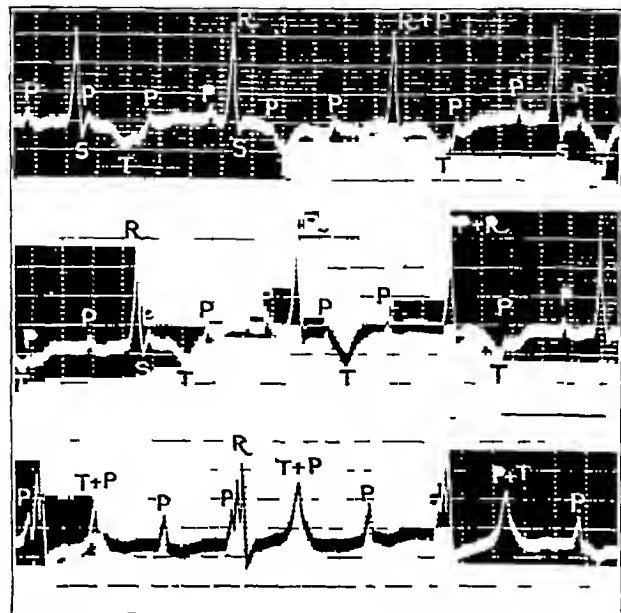

Fig 2—Complete heart block, with upright R waves in all leads and with T waves inverted in leads 1 and 2 and upright in lead 3

in five, questionable in three, slight in fourteen, moderate in eleven and marked in eleven. In some of the cases there was moderate acceleration of the rate of the auricles and ventricles with exercise, after the administra-

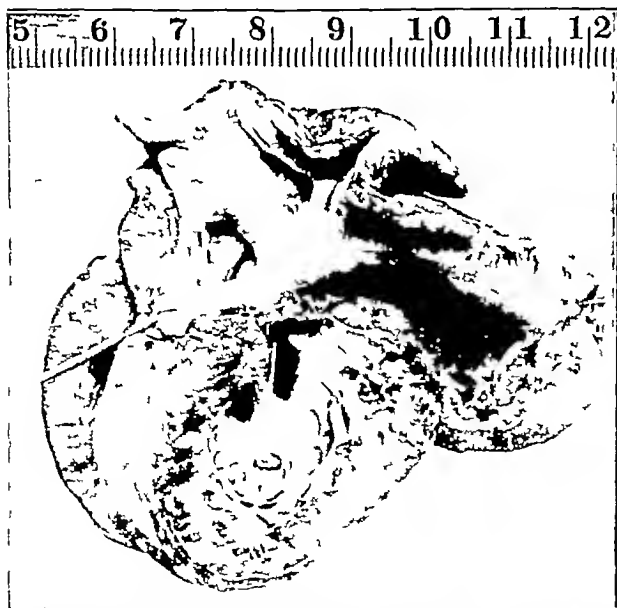

Fig 3—Right side of the heart opened showing the right auricle and ventricle. The defect in the interventricular septum is partially visible. The fossa ovalis is seen just above.

tion of atropine or during fever. A positive blood Wassermann reaction was obtained in only one case. Congenital anomalies in addition to the cardiac anomaly were present in four cases. Death was reported in eight of the forty-four cases. The deaths occurred at the

ages of 3 days, 18 days, 2 months, 3 months, 8 months, 9 years, 13 years and 20 years. Death was sudden in most of these cases but apparently was not due to congestive heart failure in any. The prognosis is dependent on the character of the congenital anomaly rather than on the presence of the heart block. It should, however, be considered serious in all cases, since a major developmental defect is probably always present to produce the auriculoventricular dissociation. The absence of a murmur does not rule out congenital heart disease, large septal defects may not present physical signs. Interventricular septal defects are not, however, entirely incompatible with fairly long life.

REPORT OF CASE 13

History—A boy, born August 16, 1932, was the mother's third child, both of the others had died in infancy, one of pneumonia, the other of meningitis. The patient weighed 5 pounds (2268 Gm) at birth. It was breast fed and took its feedings well. The mother noticed that the infant was dyspneic since birth. About five hours after birth it had an attack of cyanosis with increased dyspnea, lasting about fifteen minutes.

Fig 4—Left side of the interventricular septum, the walls of the heart having been removed. The defect is seen in the middle of the block of tissue removed for sectioning which has been replaced by the photograph. The aorta is seen in the upper left hand corner.

About one week before first admission to the Children's Hospital, September 19, it had a similar attack.

Examination—The child appeared fairly well nourished and not acutely ill. The skin and sclera were slightly icteric, and there was some cyanosis. The cervical and inguinal lymph nodes were palpable. The apex impulse was in the fifth inter-space in the usual location, apparently the heart was not enlarged. The heart rate was 48 per minute, and the rhythm regular. A loud systolic murmur was heard over the entire precordium, it was perhaps loudest over the lower portion of the sternum. The lungs appeared normal. The abdomen was soft and the liver just palpable. A patent interventricular septum was diagnosed. The infant remained in the hospital until September 28, no change occurring. The pulse rate varied from 48 to 55, the temperature being normal. An electrocardiogram was not taken at this time. Urinalysis was negative. The infant was admitted again, October 13. It had three attacks

13 Dr. Margaret Nicholson saw this patient in the outpatient department of the Children's Hospital and recognizing it as an unusual very interesting case probably of congenital heart block due to patent interventricular septum made arrangements to have the patient admitted to the hospital. Dr. E. Clarence Rice performed the postmortem examination and kindly presented the heart to us for study.

of severe dyspnea in the interim. During these attacks generalized cyanosis was present, the infant holding its breath and vomiting. Some weight had been lost and a cough had developed. Examination revealed more cyanosis, injection of the pharynx and tonsils and slight enlargement of the liver. A roentgenogram of the chest (fig 1) showed slight enlargement

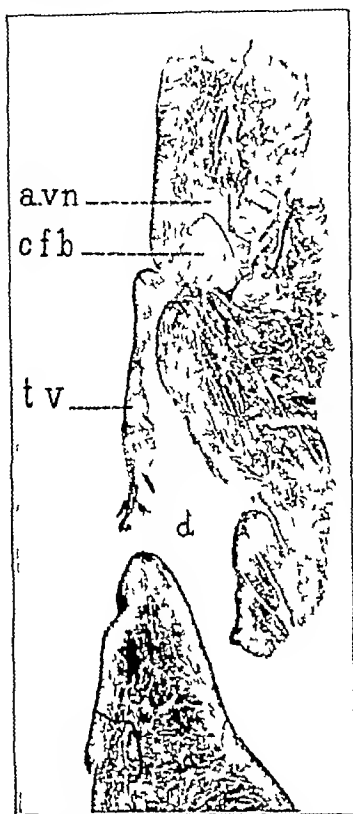

Fig 5—Section 260 showing the auriculoventricular node, a.v.n., lying on the attenuated central fibrous body, c.f.b., above the attachment of the tricuspid valve, t.v., and near the upper right hand corner of the defect, d, reduced from a photomicrograph with a magnification of 14 diameters.

of the heart and a bulge in the region of the pulmonary artery, suggestive of patent ductus arteriosus. The second day the temperature rose to 101.6 F, and each day until death was elevated at some time, reaching 105 on one occasion. The pulse rate varied between the same limits as previously. Bilateral otitis media was found and myringotomy was performed. October 18, a few fine rales were heard at the left apex and base. Albumin was present in the urine. October 19, the heart rate was 48 per minute. At this time the external jugular veins were seen to be pulsating about 120 times a minute. Heart block was diagnosed by Dr Joseph Wall. An electrocardiogram (fig 2) showed complete heart block, the ventricles beating 50 times a minute, the auricles, 150 times a minute. The R waves were upright in all leads and supraventricular in form, the T waves were deeply inverted in leads 1 and 2 and upright in lead 3. Death occurred, October 20.

Necropsy—Postmortem examination revealed bilateral otitis media and some bronchopneumonia of the left lung. The heart weighed 45 Gm. There were large and small subepicardial hemorrhages at the root of the aorta, on the left ventricle and to a lesser extent on the right auricle and ventricle. The aorta and the pulmonary artery were severed too close to the heart to show whether the ductus arteriosus was patent. When the heart was opened in the usual way, an interventricular septal defect was seen in the upper middle part of the septum (figs 3 and 4). Except for this opening the entire septum was composed of muscle, a membranous portion being absent. The defect measured about 1.3 cm in two directions. It seemed to be divided into two parts, but this was only apparent and was due to a prominence in the middle of its lower edge, which served as a papillary muscle having chordae tendineae which went to both mitral and tricuspid valves. The foramen ovale was open in its lower part. The central fibrous body was somewhat attenuated, the interauricular septum being almost entirely composed of muscle. The mitral and tricuspid valves were attached close together in the upper border of the defect. The papillary muscles were normal except for the projection already mentioned which replaced the anterior papillary muscles of both ventricles. The aortic and pulmonary valves were normal. The measurements of the heart were as follows: depth, left ventricle, 3.9 cm, right ventricle, 3.9 cm, thickness, left ventricle, 0.5 cm, right ventricle, 0.3 cm, circumference of aorta, 2.3 cm, circumference of pulmonary artery 1.5 cm, length, mitral valve opened, 3.8 cm, tricuspid valve opened, 3.7 cm.

Histologic Examination—Two blocks of tissue were removed from the heart for histologic examination. One was excised from the region of the sulcus terminalis at the mouth of the superior vena cava. This was found to contain a normal sinoauricular node. The other block was removed from the interauricular and interventricular septum, in the middle of which was the large patency (fig 4). This block contained the portion of the heart in which the main part of the auriculoventricular conduction system should be. The block was approximately a square when observed from either side, it measured 2 cm at its top and 2.2 cm at its side. The whole block was sectioned serially from left to right as the block was held with the right side forward, the block having been embedded in paraffin. In this way, the auriculoventricular node and the bundle of His would be cut transversely. The sections were about 8 microns thick. Every twentieth section of the 1,370 sections was mounted and stained by van Gieson's connective tissue stain, the intervening sections were mounted and stained as desired. The auriculoventricular node was found to be very atypical. It apparently began in its usual relationship to the mouth of the coronary sinus in the right auricle at about section 60, and was seen from that point until about section 380. The node was therefore above and to the right of the patency as the block was viewed from the right side. In this area the node slowly swelled and then became smaller again. Studied in transverse section in its thickest portion, i.e., about the middle, it appeared as a hump lying snugly on top of the attenuated central fibrous body and deeper within the interauricular septum than normally (figs 5 and 6). Its fibers were, as usual, smaller than those of the auricular myocardium and were compactly interlaced. It was not as vascular as usual, the main arteriole was largest near its beginning.

Fig 6—Section 260 showing the auriculoventricular node with higher magnification, reduced from a photomicrograph with a magnification of 70 diameters.

From this point on, the sections did not reveal any evidence of a bundle of His until about section 700, when small portions of conduction tissue were seen embedded in the fibrous tissue in the apex of the projection in the middle of the lower edge of the defect. It was impossible to decide whether these groups of fibers communicated. From section 770 to 795 there was one main bundle of fibers in the lower part of the fibrous tissue,

and this gave rise to a bundle of fibers passing downward to the right in a space in the septal musculature. This bundle was small and deeply seated. It appealed to us as being an attenuated right bundle branch. About section 800 there was an expansion of the conduction tissue in the lower edge of the defect into a compact bundle of proper size for the bundle of His. The swelling produced a little hump into the patency and was more on the left than on the right side. It gave rise to a definite left bundle branch (figs 7 and 8) which had its usual subendocardial position. The swelling gradually dis-

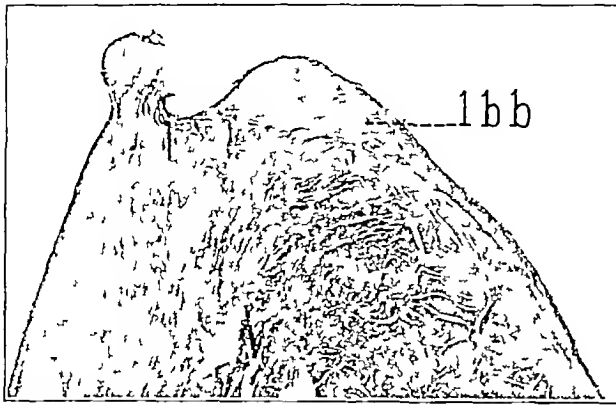

Fig 7—Section 840 showing the left bundle branch *l b b* in the lower edge of the interventricular defect reduced from a photomicrograph with a magnification of 14 diameters

appeared in further sections, but the left bundle branch was present in sections as far as section 1000 which was at the side of the patency nearest the anterior wall of the heart.

Summary of Pathologic Examination—The heart presented a large defect in the upper middle portion of the interventricular septum. In the middle of the lower edge of this defect was a muscular projection which served as the anterior papillary muscle for both ventricles. The central fibrous body was greatly attenuated and the membranous septum entirely missing. The auriculoventricular node was somewhat anomalous but was near its normal position. It did not, however, join with the bundle of His, which was practically absent, as though punched out with the defect. Small fragments of the bundle were located in the lower edge of the defect in the projection referred to. One of these gave rise to an attenuated right bundle branch. The left bundle branch was of normal size and appearance, it was located in the lower edge of the defect a short distance anterior to the right branch.

COMMENT

Some interesting points for discussion are presented by this case. One is concerned with the electrocardiographic picture. The QRS complex was of the supraventricular type, thereby indicating that the idioventricular impulses originated in the remnants of the bundle of His in the lower edge of the defect. The notching of the R wave in lead 3 was the only abnormality of the QRS complex. The large size of the T waves and their inversion in leads 1 and 2 were undoubtedly the result of the anatomic alterations in the conduction system. Whether the inversion of the T waves in leads 1 and 2 was due to the absence of the main stem of the bundle of His or to the lack of development of the right bundle branch is impossible to say. If one could say that it was due to the latter, it would be evidence that right bundle branch block is associated with this alteration of the T wave, since there is no reason to assume that there was any left ventricular strain in this case.^{13a}

The embryologic aspects of the case are important. Most cases of patency of the interventricular septum, including those with practically complete absence of the septum, are unassociated with defects of the conduction system. Monckeberg¹⁴ studied the course of the main stem and its branches in a number of hearts with interventricular septal defects. Abbott¹⁵ has summarized the reported observations of Monckeberg and other investigators as follows: "In most cases of septal defect examined, there was surprisingly little change in this normal arrangement (of the conduction system), the fibers streaming over the free border of the defect toward the apices of their respective ventricles." She explains this fact in the following way: "Investigations by Flack and Mall have shown that the interventricular septum is formed, not by a process growing upward from below, as Rokitsky supposed, but by a hollowing out of the spongy musculature of the embryonic ventricle to form the right and left chambers, the tip of the inferior septum, therefore, represents the wall of the lumen of the original cardiac tube, and this may account for the persistence of the bundle at this point in septal defects." Another important reason why so few cases of septal defect are unassociated with disturbances of conduction is the usual location of the defect. According to Abbott¹⁶ again, we find that the defects are most often "at the base of the ventricular septum just anterior to the pars membranacea, and opening on the side of the right ventricle beneath the tricuspid leaflets, or sometimes into the floor of the right auricle. Less often, they are situated more anteriorly and open into the conus of the right ventricle. More rarely still, they are in the lower part of the septum."

We are not able to visualize the events that brought about the defect of the conduction system in our case. Since the portion of the conduction system existing in this heart is of the adult type, one may assume that the

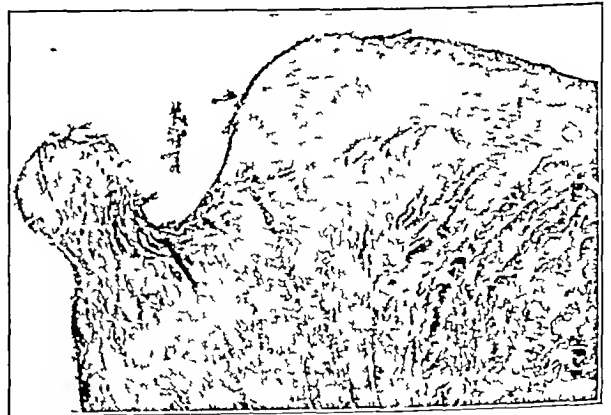

Fig 8—Section 840 showing the left bundle branch with higher magnification, reduced from a photomicrograph with a magnification of 70 diameters.

development of the system was normal except for some episode which removed the main stem. Since the membranous septum, through which the bundle of His normally passes to become the left branch, is also missing, the same episode was probably responsible for both

deficiencies This episode occurred, no doubt, after the conduction system had become a separate structure. The fact that a case has been found in which the auriculoventricular node has been separated from the rest of the conduction system lends support to Mall's¹⁷ conception that the conduction system is an embryonic rest which continues to develop independently and is not a new structure, as Retzer¹⁸ thought.

SUMMARY

A review of the literature reveals records of forty-four acceptable cases of congenital heart block, including the present report. Certain criteria have been applied in collecting these cases. In only five cases have necropsies been performed, and in only three of these have histologic studies of the conduction system been made. A congenital defect of the bundle of His appears to be the cause of this condition in most cases. The most common clinical diagnosis is patent interventricular septum. In the case here reported, there was a defect in the interventricular septum with almost complete congenital absence of the bundle of His. The case is of great significance not only as a completely studied one of congenital heart block but also as an example of the rarest form of interventricular septal defect.

CHONDROMALACIA OF THE PATELLA

FISSURAL CARTILAGE DEGENERATION, TRAUMATIC CHONDROPATHY. REPORT OF THREE CASES

JACOB KULOWSKI, MD
IOWA CITY

Chondromalacia of the patella is characterized by a circumscribed primary degenerative fibrillation, fissuring and erosion of its articular surface. It occurs as a solitary local lesion or may be associated with other common causes of internal derangement of the knee joint. In either event, it has been shown to be a definite clinical entity. Pathologically, it is a localized form of arthritis deformans (so-called hypertrophic type). Further classification is superfluous because its somewhat variable manifestations are merely differences in degree. It was first clinically recognized by Büdinger in 1906 and again in 1908, who called it "fissures of the patellar cartilage." The more appropriate term chondromalacia originated with König in 1926. The foreign literature contains numerous references to this lesion, which have been apparently overlooked by many surgeons. It is evident that recognition of patellar diseases will help to clear up some heretofore obscure derangements of the knee joint. This paper is based on three cases of chondromalacia of the patella, presenting four lesions, which have been surgically treated in this clinic since July, 1932, and are the first clinical instances to be reported in the English literature. I shall consider the local clinical aspects of this condition and its more important broader significance relative to the pathogenesis of arthritis deformans.

Chondromalacia of the patella usually occurs in the young. The history is one of chronic disability with general symptoms of internal derangement of the knee

joint. Pain, as a rule, is referable to the patella or to its immediate vicinity. The intermittent hydrops attending exertion is due to the inevitable secondary synovial sequelae. Characteristically there is localized patellar pressure tenderness in acute flexion. Subpatellar crepitus is elicited by palpation or stethoscopic auscultation. The roentgenogram reveals little of definite value even when the ulceration is markedly advanced but is strongly suggestive when slight hypertrophic changes are noted about the joint, in addition to these signs and symptoms. Roentgen examination is, however, absolutely essential for a differential diagnosis. The arthroscope, an instrument devised for the direct visualization of joints and based on the principles of the cystoscope, should gain a wider clinical application. It is evident that an exact diagnosis can be made only when the patella is adequately exposed surgically. Case 2 of this series was correctly interpreted before operation, and there are now several other patients under observation who are thought to be similarly affected. Figure 6 represents one case diagnosed as a localized patellar chondromalacia, which proved to be an advanced generalized arthritis deformans of the joint.

In mild cases the treatment consists of physical therapy and the avoidance of severe and unusual exertion. In those moderately advanced, the temporary application of a cast or brace. Operation is considered in severe lesions not affected by conservative measures. The surgical indication is excision of the involved area by curettage, or, as was performed in three of our own series, a complete resection of the patellar articular surface with its contiguous bony layer, followed by an arthroplastic toilet. This more radical procedure is simple to execute and leaves a smooth patellar surface. Operation is contraindicated in old age. Associated loose bodies in themselves are not a primary indication for operation, their surgical removal is necessary only when they cause symptoms by engaging between the articular surfaces. Similarly, osteophytic outgrowths should be removed only if they interfere with motion, give rise to or are subjected to pressure pain or are on the point of becoming detached. All other secondary pathologic changes of the joints must be dealt with as seems necessary.

Fig 1 (case 1)—A preoperative appearance of both knees; there is little to suggest the marked degenerative changes of the patellar cartilages. B the abnormal lateral mobility of the patella. C healed postoperative medial patellar incision on left.

18 Retzer R. Ueber die muskulöse Verbindung zwischen Vorhof und Ventrikel des Säugetierherzens, *Arch. f. Anat. u. Entwicklungsgesch.* 1904, p. 1.

From the Department of Orthopedic Surgery, State University of Iowa College of Medicine, service of Dr. Arthur Steindler. The term arthritis deformans, as used here, is generic and includes both great types of chronic arthritis, the hypertrophic and the atrophic.

It is important to stress certain general surgical principles with regard to the knee joint in order to avoid unnecessary repetition. A tourniquet facilitates exploration. The patient should ordinarily be placed on the operating table so that the bend of the foot piece of the table comes directly under the knee. Following

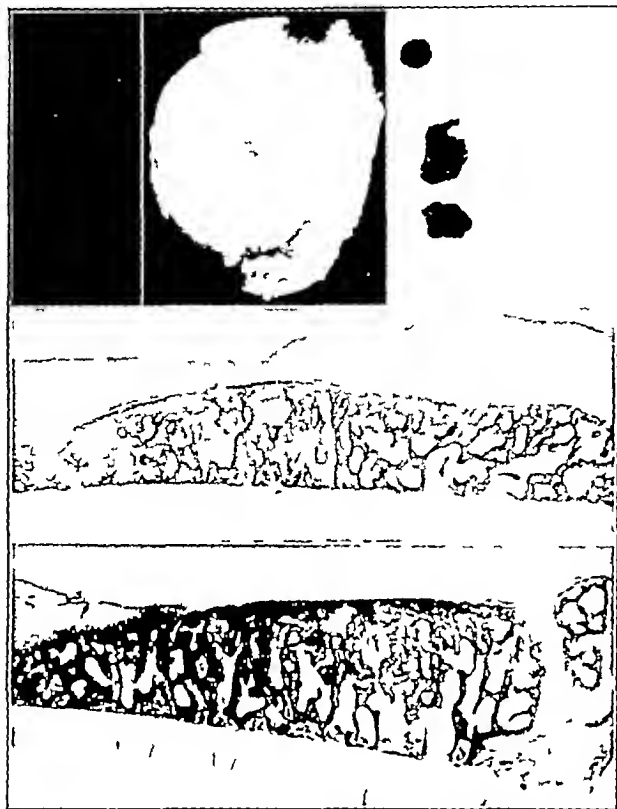

Fig. 2 (case 1)—Above, right articular surface and loose bodies removed from the right knee. Below, cross sections of ulcerated area in patella under low power.

the preparation of the limb, the foot of the table is dropped, and the leg falls with it. The operator sits on a stool and steadies the foot between his knees. It is best to employ the "general utility" medial patellar incision. The patella as well as the entire anterior part of the joint can then be everted and inspected. Probably the great majority of cases of internal derangement of the knee can be accurately diagnosed before operation, but it is in just those cases in which the cause of the derangement is doubtful that complete operative exposure is imperative. Long incisions also minimize the dangers of infection. If a complete exposure is not made, the less important, more obvious secondary joint changes will receive unwarranted attention. The most rigid aseptic technic must be observed. Towels are clipped to the skin wound edges. In order to minimize the exposure of the joint cavity, all the tissues are divided down to the synovial membrane in the entire length of the wound, and the synovial membrane is opened last. Great care must be exercised to avoid injury to the articular surfaces as well as to the ligamentous structures. The wound is closed in layers. Postoperative discomfort is minimized if all bleeding is controlled before closure. Drainage is not ordinarily indicated. A long leg cast or a posterior splint furnishes adequate temporary immobilization. Active motion and physical therapy must begin just as soon as the patient can tolerate it.

REPORT OF CASES

CASE 1—Ellen S., aged 21, single, white, a hotel clerk, seen, July 9, 1932, complained of a fairly constant dull aching bilateral patellar and general knee joint pain, which was aggravated by weather changes, bilateral looseness of the patellae (which had, however, never actually been dislocated), and intermittent swelling of the knees following exertion, which she had experienced "all her life." She was well developed and well nourished. All the joints were rather limber and allowed some hyperextension. The patellae were higher than the average normal and were loose, they exhibited definite pressure tenderness in flexion, subpatellar crepitus, and parapatellar soft tissue thickening but no increase in joint fluid. There was also present bilateral chondactyly.

Roentgenograms (fig. 1) demonstrated similar changes bilaterally: loose bodies, suggestive variegated appearance of the patellae and slight hypertrophic changes at the articular margins of the femoral condyles. The true nature of the lesion was not suspected until arthrotomy was performed of the left knee, August 30, and of the right knee, September 21. Surgical pathologic changes were similar on the two sides except that they were more pronounced on the right. Rice bodies typical joint mice and secondary synovial thickening were observed, but the remarkable degenerative condition of the articular patellar cartilage impelled attention. Slight hypertrophic changes and a tendency to partial cartilage detachment was noted over the lateral femoral condylar surfaces, probably traumatic in origin, due to the abnormal lateral mobility of the patellae. A curettage was done on the left patella, but a com-

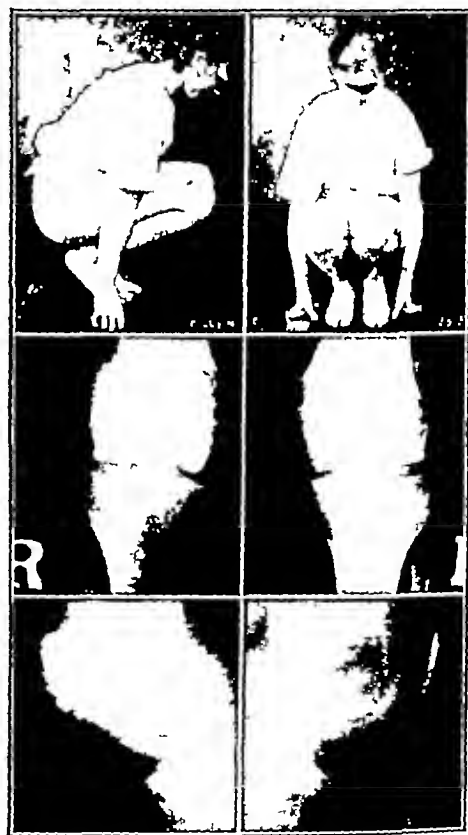

Fig. 3 (case 1)—Condition about six months after operation.

plete resection and arthroplasty followed on the right, after the patient's uneventful recovery, when she voluntarily submitted to the second operation. Because the patellae could not even at operation be easily dislocated laterally, a plasty was not considered necessary, but during closure of the wounds the deep structures were plicated. Three weeks after the last arthrotomy, some limitation of motion persisted on the left side.

which yielded to manipulation under anesthesia. Six months later the patient was symptom free and exhibited a bilateral normal functional range of motion (fig 3). The pathologic anatomy on the right side was as follows:

There was an area about three-fourths inch in diameter (fig 2) almost completely denuded of cartilage, exposing a

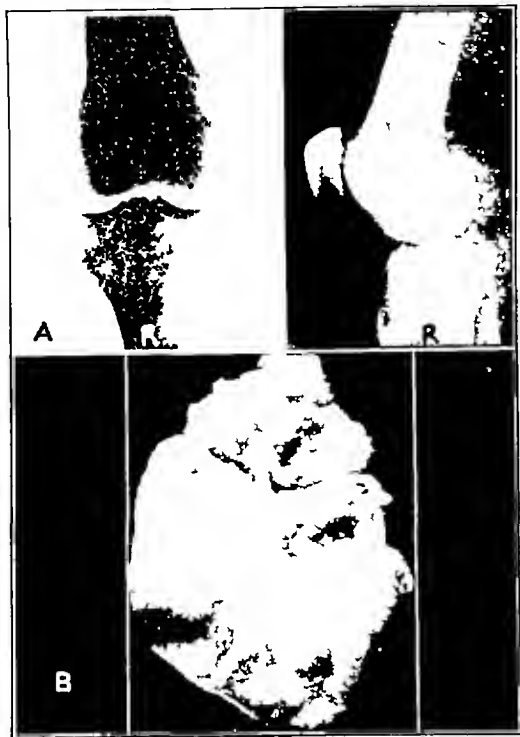

Fig 4 (case 2)—A preoperative condition, B right patellar articular surface.

smooth eburnated subchondral bony surface. A slightly bluish edematous granular appearance was imparted to such zones in the ulcerated region as were still covered in spots by very thin, highly degenerated cartilage. At the edematous margins of the crater, more or less prominent fissures radiated centrally. A marginal exostosis presented at the lower lateral border of the patella. Microscopically, the primary changes appeared as fissures and tears which vertically traversed the noncalcified cartilage to the zone of preparatory calcification at which point they frequently changed direction sharply and tended to separate the noncalcified from the calcified zone. A further degenerative feature observed was the withdrawal of the hyaline ground substance from the cartilaginous tufts between the fissures, which had become impregnated with fibrinoid. The other striking change was the proliferative reaction chiefly in the deeper cell groups of the noncalcified cartilage. The most conspicuous secondary changes in the subchondral zone were the small fractures (obviously traumatic) and defects in the zone of preparatory calcification. The contiguous marrow spaces are filled by young fibrous marrow. The marginal exostosis was typical, as were the joint mice (Giant cells were found in these mice, which must have arisen from the simple fibroblasts of the perichondrium). The synovial changes were typically those secondary to chronic joint irritation and did not show definite inflammatory infiltration.

CASE 2—Bessie M., aged 43, white, seen in May, 1932, was suffering from symptoms, over a period of four years, which clearly led to the diagnosis of multiple sclerosis. She returned in January, 1933, complaining of pain and disability of the right knee joint which followed two direct injuries about six months before. Examination elicited pressure tenderness over the patella in flexion, subpatellar crepitus and parapatellar tenderness and infiltration but no functional limitation of motion.

Roentgen examination demonstrated slight lipping of the inferior pole of the patella (fig 4). A diagnosis of chondromalacia of the patella was made and arthroscopy advised since a long period of conservative treatment had given the patient no relief, and the residual neurologic locomotor disturbance was now subordinated to the present local disability.

The degenerative changes of the patellar articular surface were at once apparent at operation. It was fibrillated in its central portion and was bordered by exostoses. The entire cartilage was edematous and lusterless. Secondary soft tissue changes were observed as well as four small loose bodies, which were removed from the intercondylar notch. One small similar area of degeneration was noted in the lateral border of the medial femoral condyle, and slight hypertrophic changes were noted over the margins of the lateral condyle. Her recovery was uneventful. She was discharged symptom free locally. Histologic studies verified the gross pathologic changes, characterized by fibrillation and erosion of its central zone. The noncalcified layer was not invaded. There were no signs of inflammation, although a slight marginal pannus was noted arising from the the synovial layer.

CASE 3—Earl S., aged 38, white, seen in June, 1929, had been ill for five years with a condition the general course of which was that of a chronic multiple infectious (atrophic) arthritis. He was treated with the usual regimen of attention to foci of infection, physical therapy and mechanical support for years, during which time the general but not the multiple joint condition greatly improved. Since 1930, the right knee localization had persistently given him the chief cause of complaint because of pain and swelling. On several occasions this joint was

Fig 5 (case 3)—A the preoperative condition B right patellar articular surface.

aspirated, and the guinea-pig tests were negative for tuberculosis. Roentgen examination showed slight atrophic changes (fig 5). A synovectomy was indicated to clear up the local residual sequelae and eradicate a possible focus of infection.

Associated with the usual rather marked soft tissue changes was the remarkable degenerative condition of the patellar artic-

ular surface. There was beginning fissuring and ulceration in its central portion, which was distinctly soft and friable. Microscopically, the articular surface was of variable thickness, and marked irregularities and fissures traversed almost the entire thickness of the noncalcified cartilage, which were radial in direction and divided the affected zone into many irregular columns. There were no signs of inflammation, even in the slight marginal pannus noted. There was very little reaction in the subchondral zone, and only the noncalcified layer was directly involved. No definite inflammatory infiltration was noted in the synovial membrane. Convalescence was remarkable only for some troublesome postoperative pain and swelling, which promptly subsided after aspiration of old blood five days later. The temperature remained slightly elevated for one week. The patient was discharged symptom free locally.

COMMENT

Chondromalacia of the patella has been definitely established as a true clinical entity. There is general agreement with regard to the morphology and treatment but not to its cause. Trauma must be assigned as the primary activating force on a background of constitutional predisposition, the poor regenerative power of cartilage and the peculiar mechanism of the knee joint.

The central portion of the patella is most poorly supplied with blood vessels, and the first changes occur here. The intrinsic blood supply of the entire patella is also generally negligible following adolescence. It is interesting to note that changes occur in the patellar articular cartilage in about 50 per cent of cases in the fourth decade, and in 33 per cent of men 20 years of age, according to Heyne and Ale-
mann. That these fissural and ulcerative conditions do

Fig. 6.—The patellar articular surface removed from an 18 year old patient diagnosed chondromalacia but proved to be a generalized form of chronic arthritis. The entire articular surface has been attacked chiefly by a pannus formation and resembles in no way the other localized forms described.

not represent an artefact is proved grossly by the presence of edema, and microscopically by the fibrinoid impregnation of the fissural walls, which latter is always present when a supportive structure is subjected to chronic traumatization, particularly pressure. The fissural formation is in all probability a consequence of chronic repeated traumas which break up the cartilage along its natural microscopic structural lines of cleavage. The normal mechanical resistance of the joint cartilage is markedly diminished because of the numerous fissures and the disappearance of the hyalinized ground substance. Many of the tufts are thereby completely separated and are free in the synovial fluid, rice bodies and even joint mice result in the biologic course of events. Essentially, however, the joint cartilage disappears by a progressive attrition of the joint surfaces until the bony lamellae are denuded. The disappearance of the articular surface then proceeds on a purely chemico-traumatic mechanism and is not caused by a pannus formation.

It is assumed, in most cases, that the pathogenesis of this condition is the key to the pathogenesis of arthritis deformans. Lawen stated that early excision of the affected area would delay or even prevent further development of arthritis deformans. This is apparently supported to some extent in more recent discussions. A study of the three cases herein presented seems to go a step further and supports the modern clinical tendency to consider the two great types of chronic arthritis — hypertrophic and atrophic — in the light that they are simply expressions of opposite ends of the same scale of a single disease (Knaggs). Both are residual end-result processes and are dependent on a variety of known factors. It is not surprising to note that there need be no sharp dividing line between the two types when the low differentiation of the tissues involved is taken into consideration. It is noteworthy, therefore, that both types of reaction have been observed in the several joints of an affected individual and, what is more striking, in the same joint.

From the mass of intensive clinical and laboratory studies devoted to chronic arthritis there stand out certain well defined and accepted causal factors in its pathogenesis: constitutional tendency, trauma, which must be broadly considered as "a series of physiological and pathological changes occurring in a joint subjected to prolonged and oft repeated injury either mechanical or toxic, but of a moderate degree of intensity," and bacterial infection. Trauma as an etiologic factor has been amply demonstrated both clinically and in the laboratory. Practically all of Koch's postulates have been fulfilled to prove the bacteriologic etiology in some forms of arthritis.

In the final analysis, it is essential to consider that all these factors may be operative in degree in a given case, and it is most difficult to separate or distinguish the predominant activating cause in most instances, particularly in adults. In this situation the residual state of the joint will depend, then, on the differences in blood supply of the bones and joints at different ages, the vitality of the tissues during the initial onset or invasion, the alterations produced by injuries whether intrinsic or extrinsic, and the invasive power of the bacteria (if or when present).

The cases presented serve to unify and give support to present knowledge of the pathogenesis of arthritis deformans. The traumatic element is definitely shown in case 1 as being due to the abnormal lateral mobility of the patellae with its consequent repeated intrinsic physiologic and pathologic mechanical insults. The trauma in case 2 was grossly direct and extrinsic. In case 3, one must assume that the hydrostatic pressure incident to the persistent hydrops exerted the injurious influences. The constitutional factor in case 1 is evidenced by the relaxed condition of the joints, and the congenital contractures of the little fingers, in case 2 by the lowered general resistance to joint injury on the basis of the cord lesion, while in case 3 this point is not clearly defined. Infection or toxins alone or combined must have played a part in case 3, but they cannot be definitely ruled out in the others. Even in the former case no definite inflammatory infiltration was noted. Of the greatest significance is the degenerative primary lesion of the patella noted in case 3, which clinically was a typical case of atrophic (infectious) arthritis. Finally, it may be stated that, at least in this localized form of chronic arthritis, the primary changes occur in the articular cartilage.

CARDIAC ASTHMA (PAROXYSMAL
CARDIAC DYSPNEA)

AND THE SYNDROME OF LEFT VENTRICULAR FAILURE

SOMA WEISS, M.D.

AND

GEORGE P. ROBB, M.D.

BOSTON

Paroxysmal dyspnea in patients with heart disease is of both practical and theoretical importance. The attacks often disable and endanger the life of patients with an otherwise apparently good state of the circulation. Unlike other types of cardiac dyspnea, it frequently occurs without exertion and without long-standing severe physical or chemical derangement of the circulation. Although its importance has been emphasized from time to time, the condition, on the whole, is obscure. Most of the available information centers on the clinical description of attacks and on statistical data relating to the nature of heart disease underlying them. The explanation of the sequence of events leading to the attack, as well as the circulatory state before and during the paroxysm, is based on inferences from clinical symptoms and signs and on post-mortem observations. The more precise study of the condition is difficult, for it cannot be reproduced in animals, moreover, in man it usually occurs at night, unexpectedly, and is of relatively short duration.

During the past three years we have been engaged in studying cardiac asthma with the aid of quantitative methods. This communication is a summary of the results of those aspects of the investigation that bear on the better understanding and management of the disorder.

LITERATURE

James Hope,¹ in 1833, was the first to use the term "cardiac asthma." In 1854, Stokes² considered the condition as an entity. Later Mackenzie³ emphasized its significance. In the German literature, Fraenkel,⁴ von Romberg,⁵ Eppinger, von Papp and Schwarz,⁶ Koranyi⁷ and more recently Gollwitzer-Meier⁸ and Goldscheider⁹ dealt with predisposing factors and the nature of the attacks. In the French school, Huchard¹⁰ and Vaquez¹¹ described the attacks.

Osler,¹² in 1897, clearly defined the condition.

In cases of advanced arteriosclerosis there are often attacks of dyspnea of great intensity recurring in paroxysms, often nocturnal. The patient goes to bed feeling quite well and in the early morning hours wakes in an attack which in its

abruptness of onset and general features, resembles asthma. There is usually a sensation of precordial distress, a feeling of constriction and oppression what the Germans call *Beklemmung*. Two other features about this form of attack will attract your attention—the evident effort in the breathing and the presence of a wheezing in the bronchial tubes and of moist rales at the bases of the lungs. The patient may spring from the bed and throw open the window in his terrible *air hunger* and he assumes an attitude most favorable to the working of all the accessory muscles of respiration. Slight cyanosis is usually present and in severe paroxysms a cold sweat breaks out in the face and limbs. The pulse is feeble, often irregular, and very small, and on auscultation one hears either gallop rhythm or the foetal type of heart beat. Death may occur in the attack.

Longcope¹³ described paroxysmal attacks of dyspnea in the presence of syphilitic aortitis, and Keefer and Resnik¹⁴ have stated that its appearance in syphilitic heart disease is due to the strain on the left ventricle from arterial hypertension and aortic insufficiency rather than to the syphilitic lesion per se.

Pratt¹⁵ has published observations and statistical data on thirty-nine cases, and as late as 1926, in referring to the nature of these attacks, he said "In discussing the causation of this condition, we are treading a dangerous ground, as quagmires of speculation lie all about us." Palmer and White¹⁶ have reported a statistical clinical study of 250 patients with cardiac asthma.

UNDERLYING CARDIOVASCULAR PATHOLOGIC CHANGES
AND AGE INCIDENCE

Of the eighty-two patients with severe attacks studied by us, 53 per cent suffered from primary or secondary arterial hypertension, 20 per cent from vascular sclerosis, particularly of the coronary arteries, but without pronounced elevation of the arterial pressure, 20 per cent from syphilitic heart disease, 6 per cent from rheumatic heart disease, and in one case the type of heart disease could not be determined. In practically all the cases studied there was clinical and laboratory evidence of hypertrophy of the left ventricle or coronary disease, or both. These data agree with other reports in the literature.

The heart rate was regular with normal sinus rhythm in 84 per cent of the eighty cases in which electrocardiograms were obtained. In 16 per cent, auricular fibrillation existed. Protodiastolic gallop rhythm was detected frequently in the group with arterial hypertension.

The electrocardiogram gave definite evidence of left ventricular preponderance in 70 per cent of the cases and of coronary disease in 38 per cent. Left bundle branch block existed in 17 per cent of the cases and intraventricular block in 5 per cent.

AGE INCIDENCE

In 71 per cent of the cases, the asthma developed after the age of 40, in 61 per cent it occurred between the ages of 40 and 79. We observed severe attacks in three instances, however, in children between the ages of 6 and 13, two of these cases were associated with malignant hypertension and one with chronic glomerulonephritis. These observations indicate that the age incidence is significant only so far as it expresses the frequency of occurrence of a type of heart disease.

associated with predominant pathologic changes of the left ventricle

CONDITION BETWEEN ATTACKS

Circulatory State—The degree of disability between attacks varied strikingly. In some of the patients studied the first and almost fatal attack occurred at night, after the usual daily labor in others there was constant disability with dyspnea and "orthopnea of necessity" requiring almost 90 degrees of elevation. A study of the peripheral circulation as measured by the stroke and minute volume output of the left ventricle, the velocity of the venous blood flow, the oxygen difference between arterial and venous blood obtained from the femoral vessels, as well as observations on the venous pressure and the absence of palpable liver and peripheral edema, indicated that in the majority of instances the peripheral circulation was essentially normal.¹⁷ In another and smaller group, the cardiac output was diminished, the velocity of venous blood flow moderately slowed and the oxygen difference between the arterial and venous blood of the extremities increased, indicating a decreased peripheral blood flow. We would emphasize that pronounced disability and orthopnea were frequently associated with normal venous pressure and adequate peripheral circulation, indicating a lack of correlation between these two functions of the circulation.

The state of the pulmonary circulation was evaluated by measurements of the volume of blood flow through the lungs and by the maximal and mean velocity of pulmonary blood flow. The method used allowed the calculation of the "crude blood volume in the lungs." The oxygen saturation of the arterial blood also served as an index of the efficiency of the pulmonary circulation. The results of these studies show that the velocity of pulmonary blood flow, particularly the mean, was usually decreased. The pulmonary dye curve was flattened and prolonged, indicating marked differences in the velocity of blood flow through the various pathways of the pulmonary circuit. There was also a tendency for the amount of blood in the lungs to be increased.

These studies with quantitative measurements have been corroborated by studies of the heart and pulmonary vessels under the fluoroscope and by roentgenograms. These observations carried out by Drs H I L. Loverud, M I Smedal and one of us (R) revealed with regularity an enlarged hilar shadow with a fanlike radiation toward the periphery and particularly toward the base of the lungs. The diaphragm was low and the excursion diminished. The border of the left ventricle showed but slight excursion, which contrasted vividly with the good excursion of the right cardiac border in the left oblique position. With effective therapy the hilar shadow caused by engorgement diminished or disappeared, the lung field became clearer, and the normal relationship between the pulsatile expansion of the two ventricles returned. Notwithstanding the intense engorgement of the lungs, râles were in many cases either few or absent, indicating lack of excessive

transudation of serum into the alveoli. In some instances with absence of râles, the large amount of blood in the lungs measured in life and found post mortem was striking.

Thus, between attacks, the pulmonary circulation showed engorgement of the vascular bed, whereas the peripheral circulation was essentially normal.

Condition of Lungs—In at least 63 per cent of the cases presenting pronounced cardiac asthma the clinical examination of the lungs showed marked signs of emphysema, such as increased anteroposterior diameter of the thorax, increased resonance, diminished breath sounds, partial or complete obliteration of the absolute cardiac dullness and diminished movement of the diaphragm. In 10 per cent of the cases, bronchitis or bronchiectasis was also present. The total volume of the pulmonary air space was usually diminished with an average of 4,442 cc instead of 6,760 cc. The vital capacity was considerably diminished, it was 2,406 cc instead of 4,940 cc. The average value for the residual air was 2,036 cc instead of 1,820 cc, and the ratio between the vital capacity and the residual air was 1.18 instead of 2.8 found in normal subjects.

These changes in the pulmonary air spaces can be explained, to a large extent, as being secondary to circulatory changes in the pulmonary vessels. In a control group of cardiac patients without asthma and with a greater degree of disturbance in pulmonary circulation, we often observed a lesser degree of disturbance in the physiologic state of the air spaces than in the cases presenting cardiac asthma, in the latter group, therefore, secondary functional emphysema is superimposed on a chronic emphysema. The existence of this secondary emphysema, as a result of engorgement and capillary hypertension of the pulmonary circuit, has also been substantiated by the observation of a constant improvement between the vital capacity-residual air index and vital capacity under rest, digitalis and dehydration therapy.

THE ATTACK

The clinical appearance of the paroxysm has been described classically by Hope, Stokes, Osler, Romberg and others. We comment on certain aspects heretofore insufficiently appreciated. The majority of attacks are associated with both inspiratory and expiratory distress, and with rhonchi and moist râles. The respiratory midposition of the thorax becomes elevated and there is a tendency for the chest to become fixed in a forced inspiratory position so that respiration is almost entirely diaphragmatic. In one case, during an extreme attack, the respiration ceased with the thorax held rigidly in a high inspiratory position that at first resisted artificial respiration. During attacks there is also a striking inspiratory retraction of the entire lower half of the thorax, most marked in the intercostal spaces. The degree of pulmonary edema usually depends on the severity and duration of the attack. Patients with low plasma protein are particularly apt to develop severe pulmonary edema. The pulmonary second sound becomes greatly accentuated, and often, even in the presence of marked hypertension, is louder and more ringing than the aortic second sound. With the cessation of the attack the original relationship between these heart sounds is restored. The color of the skin, particularly in severe attacks is ashen rather than cyanotic. The small cutaneous veins are collapsed and the larger veins are small and apparently constricted. A "cold sweat" usually breaks forth and in severe seizures may drench the patient.

¹⁷ The methods used were (a) for volume, velocity of the blood flow Moore J W Kinsman J M Hamilton W F and Spurling R G Studies on the Circulation II Cardiac Output Determinations Comparison of the Injection Method with the Direct Fick Procedure. *Am. J. Physiol.* 80:331 (July) 1929. Robb G P and Weiss Soma A Method for the Measurement of the Velocity of the Pulmonary and Peripheral Venous Blood Flow in Man. *Am. Heart J.* to be published. (b) For lung volume Van Slyke D D and Binger C A L The Determination of the Lung Volume Without Forced Breathing. *J. Exper. Med.* 37:457 (April) 1923. (c) For the venous pressure, Moritz F and Tabora D V Ueber eine Methode beim Menschen den Druck in oberflächlichen Venen exact zu bestimmen. *Arch. f. klin. Med.* 98:475 1910.

In a number of cases, particularly with syphilitic aortitis, there was intense dyspnea and tachypnea without characteristic asthmatic breathing or the usual signs of pulmonary edema. Patients with aneurysmal dilatation of the aorta and pressure on the trachea or bronchi on the other hand, tended to develop particularly severe bronchospastic attacks. Patients with mitral stenosis did occasionally develop an asthmatic type of respiratory distress but lacking autopsy evidence we cannot state with certainty that aortic disease with left ventricular hypertrophy and coronary disease are not causative in such cases. The character of these attacks differs from the classic cardiac asthma.

The association of cardiac asthma and precordial pain was rather frequent, and in some instances precordial pain with classic anginal radiation and asthma developed independently in the same patient. Instances were also observed of severe attacks of asthma, rather than pain, accompanying coronary thrombosis. Contrary to the general belief as well as to statistical data in the literature, cardiac asthma in its milder form was found to develop frequently at a certain stage of heart disease. Nocturnal periodic nervousness, cough, paroxysmal pounding of the heart and Cheyne-Stokes breathing are equivalent manifestations of mild cardiac asthma, often they are forerunners of severe cardiac asthma.

Circulatory State—The heart action during an attack was invariably rapid, with a tendency to embryocardia, but arrhythmias as a rule did not develop. In three instances in which electrocardiograms were obtained during seizure, no essential change in conduction time, ventricular complex or the electrical axis was observed.

The peripheral circulation during attacks showed variable changes. Usually the volume output of the heart either remained the same or became decreased, in no case was there an increase. The oxygen difference between the arterial and the venous blood of the extremities showed no constant change. There was a tendency for the velocity of the peripheral venous blood flow to be absolutely or relatively increased. The arterial blood pressure, with rare exception, was elevated, usually to a striking degree. The venous pressure remained the same as before the attack or became moderately elevated. The oxygen saturation of the arterial blood became slightly or markedly reduced, depending on the severity of the pulmonary edema and bronchospasm, at times such low values as 40 to 50 per cent of saturation were obtained. Thus, although in the very severe and prolonged attacks particularly there was venous congestion with normal or reduced velocity of blood flow, it is significant that the venous pressure and the velocity of the peripheral blood flow usually remained fairly normal.

The pulmonary circulation was characterized by intense engorgement and hypertension. A distinct accentuation of the pulmonary second sound usually occurred. The volume of blood flow through the lungs during the attacks generally remained unaltered or was decreased. The velocity of the pulmonary blood flow was regularly diminished during the attack, this was particularly true of the mean velocity of blood flow as indicated by the prolongation of the dye distribution curve. These changes together with the tendency to pulmonary edema, indicate that the main characteristic of the pulmonary circulation during an attack is not an alteration in the volume of blood flow through the lungs but rather an increase in the volume of the pulmonary vascular bed and relative stagnation of blood,

with acute hypertension of the pulmonary circuit and transudation of serum. Thus, the difference between the peripheral and the pulmonary circulation already noted between attacks becomes further accentuated during the attack.

Condition of Lungs—The clinical character of the respiration has been referred to. A forced inspiratory position of the thorax with evidence of pulmonary congestion, later with edema and spasm of the bronchi, is present. The lungs appear to be overdistended. The orthopnea usually becomes maximal. Measurement of the lung volume and residual air during the attack is not feasible, but the fact that the vital capacity is considerably further reduced even in the milder attack without gross bronchospasm, indicates that the physiologic state of the air spaces, and thus the aerating function of the lungs, is acutely disturbed. The oxygen unsaturation of the arterial blood often of marked degree, is an evidence of the poor pulmonary ventilation of the lungs. The low position of the diaphragm, with high inspiratory position of the thorax speaks for an increase in the volume of the thorax during the attack. This increased thoracic volume is occupied in part by increased amount of blood in the vascular bed in part by transudation of edema fluid into the pericapillary and intra-alveolar space, and, in addition, probably by an increase in the total volume of free air space. Thus an acute functional emphysema is precipitated and superimposed on the preexisting emphysema. Such an unfavorable relationship between the pulmonary circulation and the bellows function of the lungs creates a situation which obviously leads rapidly to a state of suffocation.

PRECIPITATING FACTORS OF ATTACKS

One of the most perplexing aspects of the problem is the understanding of the factors which precipitate the attack in a patient with a predisposing derangement of the cardiovascular and nervous systems. A knowledge of these factors, as well as of those leading to cessation of the paroxysm, should throw much light on the nature of the condition.

There are several factors that definitely lead to the attack. Although the paroxysm can occur during the day, particularly in advanced cases, it usually occurs at night. The horizontal position of the body is one of the most important factors in this nocturnal character of asthma. This is shown by the fact that when patients are in the high, "pillowed-up," position attacks are less apt to occur, and that standing regularly gives relief. Patients discover prompt relief after rushing to the window, drinking water or brushing their teeth, but the common feature in these measures is the change from the horizontal to the upright position. Some of the patients dread to go to bed, some, with severe attacks prefer even to stand up, leaning forward, throughout the night. We have had an opportunity to study several patients who, as soon as the thorax was lowered below a certain critical angle of orthopnea, invariably developed increasing signs of congestion, accentuation of the pulmonary second sound, elevation of the arterial pressure, Cheyne-Stokes respiration, rales wheezing and finally typical but mild seizures. These observations together with the fact that change from lying on the back to lying on the abdomen with the same angle between the thorax and the body resulted in cessation of the attack and increase in the vital capacity indicate that the angle and the position of the thorax rather than of the entire body have an

important bearing on the sequence of events within the thorax leading to attacks

Patients with marked left ventricular disturbance frequently develop Cheyne-Stokes breathing at night. The periodic circulatory changes during the two phases of the respiration, together with the sudden awakening with excitement in the beginning of hyperpnea, during which the inspiratory position of the thorax becomes progressively increased, easily lead, in the already over-filled pulmonary circuit, to acute pulmonary congestion and attack. Noise, nightmare, paroxysms of coughing caused by gradual accumulation of mucus in the respiratory passage during sleep, the urinary reflex, and other factors may induce a change from a state of relative depression to sudden hyperexcitability of the vasomotor, cardiac and other centers. Such factors act as triggers in precipitating an acute and temporary imbalance between the functioning of the right and left ventricle, a heightened pulmonary congestion with acute pulmonary vascular hypertension resulting finally in pulmonary edema.

The water content of the tissues is also an important although not a primary factor in the precipitation of seizures. Patients subject to cardiac asthma often exhibit slight water retention in the form of physiologic edema while active during the daytime. During the night, when recumbency with its lowering of the peripheral hydrostatic pressure facilitates the entrance of fluids from the tissues of the extremities into the blood stream, the site of water retention tends to be transferred to the lungs. We have obtained evidence that, in the early stage of the attack particularly, the water content of the arterial blood is somewhat diminished as compared with that of the venous blood, indicating a loss of fluid into the lungs. Often the induction of slight diuresis results, all other factors being equal, in the prompt cessation of recurrent attacks.

In addition to these emotional reflexes and physical factors, our observations indicate that histamine, ergotamine and anoxemia can at times induce mild seizures. From the foregoing analysis, it is clear that several factors must operate in the development of cardiac asthma.

FACTORS LEADING TO CESSATION OF ATTACK

We have summarized elsewhere our experiences with effective therapeutic measures in cardiac asthma.¹⁸ It was emphasized that the modus operandi of all the efficient physical and chemical agents depended on their capacity to relieve the pulmonary hypertension and improve the function of the left ventricle: (a) through reducing peripheral venous return (venous stasis with tourniquets over the extremities, elevation of the body, or venesection), (b) through decreasing peripheral vascular resistance (glyceryl trinitrate, stimulation of the carotid sinus, small doses of epinephrine, at times atropine), (c) through improving the coronary blood flow (glyceryl trinitrate, small doses of epinephrine, digitalis bodies, at times large doses of atropine), (d) through relaxing the bronchioles (epinephrine, ephedrine, lobeline, atropine), (e) through abating excitement and depressing reflexes (morphine). Thus, effective measures are those which influence favorably at least one important part of this complex vicious circle and hence tend to reestablish normal pulmonary circulation and left ventricular function.

Just as in the precipitation of attacks the ventricular imbalance develops suddenly, so the therapeutic measures that are capable of reestablishing the balance between the two ventricles and eliminating the acute pulmonary engorgement can improve the clinical condition with surprising rapidity. We have frequently observed relief and the disappearance of attacks within from two to three minutes after the application of tourniquets over the extremities.

The mechanism leading to spontaneous improvement is apparently not uniform. In the majority of instances of moderate attacks, the patient jumps out of bed and by assuming an upright position obviously decreases the venous return to the heart and thus improves the pulmonary circulation by allowing the left ventricle to deplete the excessive volume of blood in the lungs. One also often sees the patient leaning forward with the head bent on the chest during the attack and experiencing partial relief, in this position, too, the venous return is impaired and therefore the mechanism of improvement is the same. In addition, bending and lowering of the head may induce favorable vasomotor and circulatory reflexes.¹⁹ In the severe attacks, on the other hand, there may be a secondary failure of the right ventricle with spontaneous venostasis, and, finally, in extreme attacks, all the clinical and circulatory manifestations of shock may supervene. The heart rate becomes rapid, the venous return through peripheral pooling of blood is decreased, and the arterial pressure falls. This secondary failure of the peripheral circulation in extreme attacks with shock gives the left ventricle an opportunity to recover and take care of the overburdened pulmonary circuit. Here is an example of a regulatory mechanism in disease in which one type of serious derangement induces another, which in turn indirectly rectifies the first imbalance.

PREVENTION OF ATTACKS

Measures that improve the reserve functional capacity of the left ventricle, decrease the excitability of the cerebral centers, prevent pulmonary congestion, decrease capillary permeability and transudation, and eliminate nocturnal restlessness are efficient therapeutic measures. The technique of the administration of digitalis substances, the importance of dehydration, and the role of high protein diet and of other measures have been discussed before.¹⁸

PROGNOSIS

Attacks of cardiac dyspnea offer a serious prognosis. Out of eighty-seven patients with pronounced and classic attacks, forty-four were known to be dead within one year after observation. Studies of the records of a number of other cases indicate, however, that exceptions with attacks of several years' duration are not rare. Not infrequently, with the onset of right-sided congestive failure, the attacks may even disappear, often to recur when the peripheral circulation again becomes normal. The presence of pronounced bronchospastic tendency during attacks offers relatively better prognosis. Patients with left ventricular disturbance not infrequently develop asthma with respiratory infections which temporarily or permanently disappear with the disappearance of the pulmonary infection. In these cases the bronchial infection predisposes to broncho-spasm and therefore lesser grades of circulatory change precipitate the seizure. Such an attack, although of

¹⁹ Weiss, Soma and Baker, J. P. *The Carotid Sinus Reflex in Health and Disease: Its Role in the Causation of Fainting and Convulsions*. Medicine to be published.

somewhat different significance, is, in our opinion, of the same nature as classic cardiac asthma. The difference lies only in the predominance of the bronchospastic or circulatory disturbance. The differentiation of primary bronchial asthma from cardiac asthma is often difficult and at times cannot be made.

COMMENT

The disturbed balance between the coronary blood flow and the metabolic requirement of the muscle of the left ventricle, as compared with the right ventricle, is the primary factor in the pathogenesis of cardiac asthma. As a result, the reserve functional capacity of the left ventricle becomes disproportionately impaired, and later, according to the observations presented there follows a back pressure effect within the pulmonary circuit, usually without failure of the peripheral circulation. In this engorged state of pulmonary circulation the reserve pulmonary vessels are taken up by blood, and pulmonary vascular hypertension of moderate to severe degree develops. It has been demonstrated that these circulatory changes then induce a functional emphysema of the lungs. Our studies with quantitative measurements in man, therefore, confirm the theory proposed by von Basch²⁰ some fifty years ago on the stiffening effect of the circulation on the lungs. In addition to this functional emphysema, a primary organic emphysema and bronchitis with a bronchospastic predisposition is frequently encountered in patients with cardiac asthma. Sleep with the body and particularly the thorax in the horizontal position results in additional pulmonary engorgement. The coronary circulation in sleep in the horizontal position can only be surmised. Consideration of the pulmonary hemodynamics, however, suggests some hindrance to the coronary arterial inflow as well as the venous return, particularly through the thebesian veins.

It is then on these predisposing bodily states that the precipitating factors act as triggers. Excitement with fear, and sudden hyperactivity of the autonomic brain centers, accompanying the precipitating factors discussed, result in the sudden simultaneous elevation of the arterial pressure and constriction of the small venules controlling the blood depots of the body. We have obtained evidence that chemical substances such as epinephrine and histamine and choline exert a pronounced vasomotor effect on the venules.²¹ The sensitivity of the venules to histamine is even greater than that of the arterioles. Thus, reflexes and chemical substances induced by the precipitating factors cause a sudden increase in the peripheral vascular resistance and simultaneously an increase in the venous return. These factors acutely embarrass the already impaired left ventricle, which is unable to respond to the emergency because its ischemic state is now intensified by further impairment of the coronary circulation from coronary spasm and from obstruction to the coronary venous return as a result of the suddenly increased pressure in the right side of the heart. This most unfavorable circulatory state leads to an acute accentuation of the left ventricular embarrassment which in turn results in an acute generalized pulmonary vascular hypertension. In order to be compatible with life, the duration

of the acute failure of the left ventricle can last but a short period of time, in the order of seconds or minutes. Following this, the vital balance between the ventricles as far as blood flow is concerned is reestablished, but with continued disturbance within the pulmonary circuit. The blood in the lungs remains trapped and therefore the dyspnea continues after the ventricular balance is reestablished. The balanced ventricular function is maintained now with a new circulatory adjustment in the lungs. For the relief of the attack it is essential, therefore, that the left ventricle be capable of throwing out more blood from the lungs than the right throws in. Measures such as venostasis induce such a situation promptly, hence, they relieve attacks rapidly. In spontaneous relief, this is accomplished more slowly. Improvement of other aspects of the attack, such as the disappearance of edema and stiffening of the lungs, takes a longer time. We have observed in both patients with cardiac asthma and with other types of cardiac disease that a restoration of the pulmonary hemodynamics long preceded the disappearance of "functional circulatory emphysema."

Clinical signs, measurements of the pulmonary air spaces and pharmacologic observations revealed a bronchospastic element in cardiac asthma. In a number of instances with classic cardiac asthma, we have observed a large number of eosinophilic leukocytes in the sputum and less often in the blood. Thus, cardiac and bronchial asthma behave similarly in these respects, although the underlying structural and physiologic changes differ.

Heberden²² has stated that angina pectoris is not associated with embarrassment of the respiration, we have presented, on the other hand, a number of parallelisms existing between the underlying etiology of cardiac asthma and angina pectoris. It is probable that in the typical cases of angina the respiratory distress is absent because of lack of previous pulmonary engorgement and predominant pathologic changes in the left ventricle, and because during the attack the function of the two ventricles becomes involved to the same degree, hence acute pulmonary engorgement does not develop. This is also corroborated by the behavior of the patient who, with classic angina but without paroxysmal dyspnea, following left coronary thrombosis develops cardiac asthma.

Our studies have not revealed as yet the more intimate role of chemical substances and reflexes in the mechanism of the attack. Reflexes probably play a particularly significant role.²³ In three instances we have blocked the vagus nerve with procaine hydrochloride, which resulted in improvement of the dyspnea, orthopnea, elevation of the vital capacity and ipsilateral disappearance of rhonchi and rales, and improvement of the breath sounds.

Measurements of the blood flow between and during an attack did not confirm the contention of Eppinger, von Papp and Schwarz²⁴ that during an attack the cardiac output is considerably increased. Such changes did not exist and, in our opinion, are not the center of the problem. We also failed to find any basis for a separation of cerebral asthma from cardiac asthma as suggested by Romberg.²⁴

24 von Romberg Ernst Ueber kardiales und cerebrales Asthma Wien med. Wchnschr. 80 361 (March 8) 1930

The clinical, structural and physiologic characteristics observed between attacks are the expressions of a subacute or chronic failure of the left ventricle, those during attack, of an acute failure. Some aspects of the left ventricular failure have been discussed in greater detail before.²⁵

On the basis of the joint clinical and laboratory evidence, one can definitely state that the *syndrome of acute or subacute left ventricular failure*, suggested and discarded by a number of clinicians during the past century, exists and plays a fundamental role in a large group of patients with heart disease. The syndrome is characterized by relative or absolute insufficiency of the left coronary circulation, such as chiefly exists in arterial hypertension, coronary sclerosis and thrombosis, and in syphilitic aortitis. It is accompanied by a tendency to protodiastolic gallop rhythm, electrocardiographic evidence of left ventricular preponderance and changes in ST complexes indicating coronary and myocardial disease. Bundle branch block occurs in an appreciable percentage of the cases. Clinically there is also evidence of emphysema of the lungs with orthopnea and often with accentuation of the pulmonic second sound. During sleep, Cheyne-Stokes breathing is often present. Roentgen examination of the lungs reveals an increased hilar shadow with fanning out toward the periphery, the result of pulmonary congestion. The pulsatile expansion, as observed by fluoroscopy, of the left ventricle is relatively small, whereas the right ventricular activity is normal or increased. Notwithstanding the marked disability of the patient, as shown by dyspnea and orthopnea, the failure of the peripheral circulation, as evidenced by the lack of engorged veins, the absence of palpable liver, and peripheral edema, is slight or completely absent. Depending on the degree and rapidity of the failure of the left ventricle, and on the state of the right ventricle, these clinical manifestations show much variation.

In this presentation we have focused our attention on changes in the circulatory and pulmonary systems, these being of the greatest importance. Obviously, changes in other organs have also an important bearing. The rôle of the central nervous system is particularly important. Alterations in the diseased cardiovascular system by various emotional states has been demonstrated previously.²⁶ We were impressed by the bearing on the attacks of mental stress, fear and subconscious mental activity during sleep. Among the effective therapeutic measures, psychotherapy is important. Thus, in cardiac asthma, physical and chemical as well as emotional and reflex factors are in constant interaction, and measures that influence these factors singly or combined can bring relief.

SUMMARY

1 A study of the dynamics of the peripheral and pulmonary circulations in cardiac asthma is presented, and the relation of the circulation to clinical symptoms and signs of left ventricular failure and to the mechanism of asthmatic attacks is described.

2 Whereas the peripheral circulation between attacks of cardiac asthma is usually normal, the pulmonary

circulation exhibits engorgement and evidence of pulmonary hypertension.

3 Simultaneous measurements of the lung volume and its subdivisions, and the pulmonary circulation between attacks reveals a functional pulmonary emphysema caused by disturbance of the pulmonary circulation.

4 With improvement the pulmonary circulation first becomes normal, followed by disappearance of the functional emphysema.

5 In the precipitation of attacks, the coexistence of subacute failure of the left ventricle and acute precipitating factors is essential.

6 Acute pulmonary hypertension, a secondary intense functional emphysema, and pulmonary edema are the main features of the attacks. The volume of the blood flow through the lungs is normal or decreased, the velocity usually decreased.

7 The pulmonary rather than the peripheral circulation is related to orthopnea.

COMPLICATING POLLEN FACTORS ENCOUNTERED IN RAGWEED HAY FEVER

AN ATMOSPHERIC STUDY

O C DURHAM

NORTH CHICAGO, ILL.

Pollen therapy, as developed during the past two decades, is not a process—it is a study of individual susceptibility to pollen, individual contact with pollen and individual response to specific pollen extracts. Since Duke¹ has shown that susceptibility to pollen is largely a matter of the relative amount of pollen with which the patient has come in contact and since the patient's response to pollen therapy is influenced by the amount of pollen, success in the study of individual hay fever cases is partly dependent on factors outside the physician's control and often outside his knowledge and experience. It is safe to assume that a large part of the poor results in pollen therapy is due to basic botanic causes. The choice of pollen or pollens to be used in the diagnosis and treatment of a hay fever sufferer is really a question of that patient's daily and seasonal quantitative contact with known toxic pollens.

Much effort has been expended during the past fifteen years in attempting to solve this fundamental problem of pollen contact. Usually the approach has been indirect, the emphasis being placed on the geographic distribution of hay fever weeds. Many, but not nearly enough, local and general botanic surveys have been made, but the resulting lists of plants have often been impracticable, because no real evidence was offered as to the relative amounts of the various pollens actually found in the air. In a list, one plant looks as important as another. Even Thommen's² five postulates for evaluating possible hay fever plants cannot be applied with any degree of precision. It is apparent that an accurate knowledge of the relative amounts of all hay fever pollens found in the air throughout the year will answer most of the botanic questions arising in the practice of pollen therapy. This is the direct approach.

to the problem. Fortunately it is being found that atmospheric studies tend to simplify rather than complicate the issue.

In keeping with its relative importance, ragweed has received most of the attention in previous atmospheric pollen surveys. This study is the first attempt to evaluate quantitatively the pollens of secondary importance throughout the ragweed area. It is the outgrowth of an intensive four-year study of the national ragweed pollen situation, which accounts for the fact that slides were not exposed before August 10, as would be necessary for a complete picture of the behavior of such pollens as Russian thistle and hemp, whose seasons begin before that of ragweed. For the same reason, the geographic limits are not inclusive for sages and other western pollens whose territories extend beyond the ragweed area. These atmospheric observations are supported by field work, as I have had the privilege of making careful examinations of the hay fever flora in and about almost every city in which slides are exposed. While the study embraces data for only one year the results have added significance because of the fact that these pollens have been studied on the ragweed slides and, in some instances, I have counted them for several years. The value of these one-year statistics is also enhanced by the knowledge of the behavior of ragweed at these same locations over a four-year period.

This is the first attempt to evaluate on a nation-wide scale the pollens of secondary importance in the ragweed area during the ragweed season. Most of the statistics were obtained by making differential counts on all pollen slides exposed during 1932 at stations of the United States Weather Bureau, the Canadian Meteorological Service and the Mexican Meteorological Service. In several instances, figures for other years have been included and in a few instances data are drawn from the reports of other workers. In all cases exposures began on August 10 and continued as long as appreciable amounts of pollen were found in the air. The methods of exposure and counting have been described in my previous articles.³ The proportions shown here are based on the total number of pollen granules of each kind found on the usual unit area of slide surface throughout the season.

In the eastern part of the United States the fall pollen problem is comparatively simple. In a number of Eastern cities ragweed constitutes more than 98 per cent of the total fall pollen crop. This finding is in accord with that of Acquarone and Gay⁴ at Baltimore. In the Middle West there is a much larger percentage of pollen from other sources than ragweed, in some cases more than 50 per cent. The country may be sharply divided at the fifty-ninth meridian (east edge of Kansas) into an eastern region where ragweed is almost the only fall pollen and a western region where Russian thistle, western water hemp, Kochia, or the sages are often as important as ragweed.

RAGWEED FAMILY

Rather extensive reports have been made on the distribution of ragweed in North America during the past four years. No attempt has been made in previous studies to determine the proportion of ragweed pollen coming from the various species of ragweed (*Ambro-*

siaceae), pollen from all species of the four genera being counted as "ragweed." Short ragweed (*Ambrosia elatior*) and giant ragweed, known also as horseweed (*Ambrosia trifida*), are well distributed throughout almost the whole area studied and are of course more concerned in the total pollen crop than all other plants taken together. Of the two, short ragweed is the more important.

The only other ragweed pollen of wide geographic distribution is that of cocklebur (*Xanthium* spp.). It is found throughout the area studied, but since the quantity is so small, a separate record was not made. It appeared most often on slides from the South Central states during August.

In counting, only burweed marsh elder (*Iva xanthifolia*) was differentiated from the other ragweed pollens. It was found to be most abundant in the Dakotas, Nebraska and Colorado. It is also found west of these states.

Chenopod and amaranth were not differentiated except in the case of Russian thistle and Kochia. Russian thistle (*Salsola pestifer*) was found to be abundant in South Dakota and Colorado but was found as far south as Amarillo, Texas, where it is the principal offender. Omaha marks the practical eastern edge of its range. Kochia or Mexican firebush (*Kochia scoparia*), is found in the same area as Russian thistle and it is most abundant in western Nebraska, where it constitutes more than half of the pollen content of the air.

Western ragweed (*Ambrosia psilostachya*) is common west of Wichita and Oklahoma City and on the Mexican border. Marsh elder (*Iva ciliata*) thrives in the South Central states and southern ragweed, or lance-leaved ragweed (*Ambrosia bidentata*) is found throughout the most of Missouri, southern Illinois, eastern Kentucky and Tennessee and part of Arkansas. Separate reports were not made for these ragweeds. To determine their exact role is difficult but not impossible and, no doubt, will be worked out later.

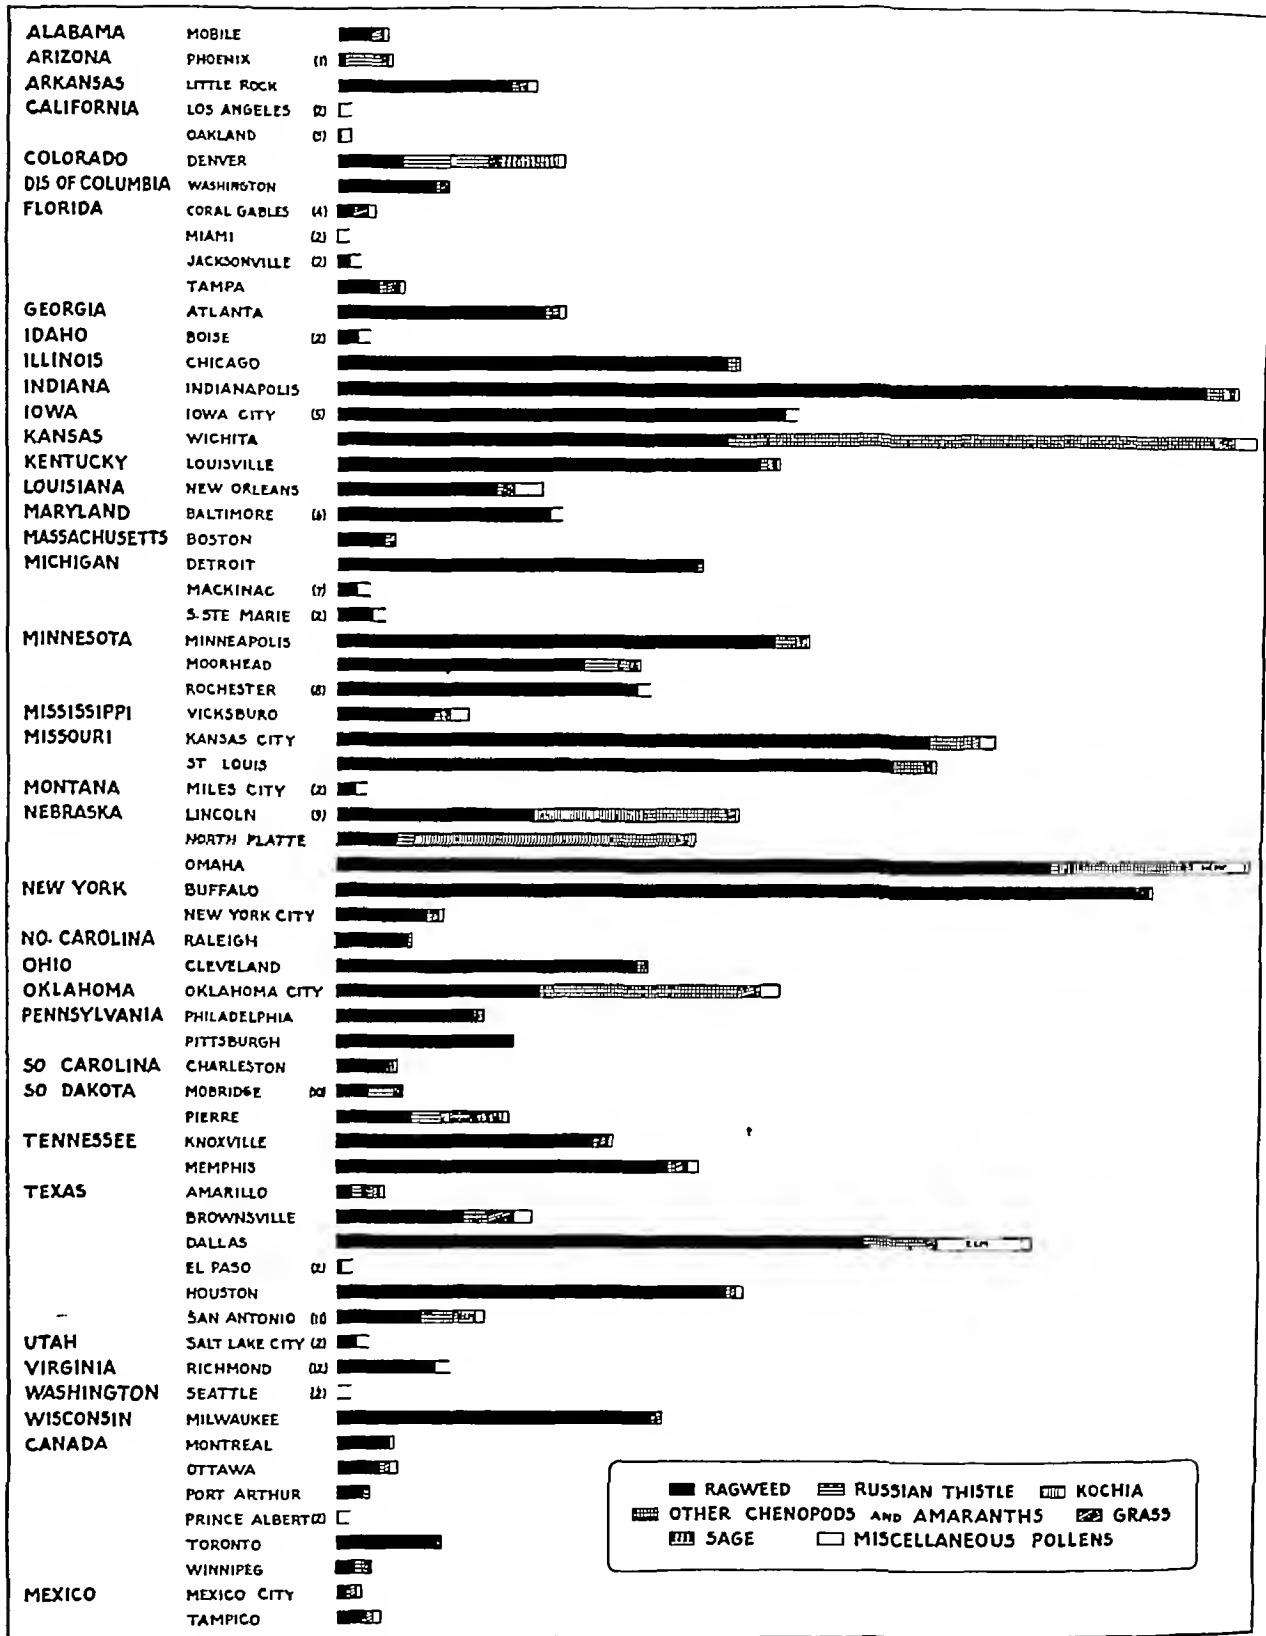

The only ragweed pollen readily distinguishable from other ragweed pollens and found in important quantities is that of burweed marsh elder (*Iva xanthifolia*), variously known throughout the Northwest as "high marsh elder," "tall poverty weed," "prairie ragweed" and "horse weed." This study shows it to be important in the Dakotas, Nebraska and Colorado. Omaha had the largest amount of this pollen but Denver had the largest proportion. Burweed marsh elder is common in but not around Chicago. On slides exposed on the Federal Building in the Chicago "loop," the proportion of burweed marsh elder pollen settling out of the upper air was exactly 1 per cent of the total ragweed deposit. Exposures near the ground and near the weeds have a much greater proportion of this pollen. This is an excellent demonstration of the fact that after all the pollen content of the upper air above even a large city is determined more by the hinterland than by the city areas themselves.

CHENOPOD

The practical distribution of these pollens is regional, rather than general, although there is one member—lamb's quarters (*Chenopodium album*)—which is found in large amounts throughout the cultivated districts of North America. That lamb's quarters is not important in the eastern part of the United States is proved not only by the small amount of pollen in the air but by the experience of allergists practicing in that area.

C.; 3 A Study of the Atmospheric Pollen and Botanic Flora of the East Shore of San Francisco Bay J. Lab. & Clin. Med. 13: 416 (Feb) 1928; 4 Nicholson E. S. and Durham O. C. A Pollen Survey of Miami, Florida South. Med. J. 24: 947 (Nov) 1931; 5 Unpublished data for ragweed only (1928-1930) cooperation of Dr. Zella White Stewart; 6 Acuarone and Gay; 7 Unpublished data for ragweed only (1929) cooperation of Dr. Siegfried Maurer; 8 Ragweed data only (1928) cooperation of Dr. C. K. Maytum; 9 Unpublished data (1928) cooperation of Dr. Paul Black; 10 Unpublished data (1932) cooperation of Dr. G. H. Twining; 11 Unpublished data (1929-1930) cooperation of Dr. I. S. Kahn; 12 Ragweed data only (1928) cooperation of Dr. Warren T. Vaughan.

In this group, as in the ragweed family, the pollens are so similar microscopically that only a few of the members of the group may be easily distinguished. Those most readily identified are Kochia, or Mexican firebush (*Kochia scoparia*) and Russian thistle (*Salsola pestifer*). Western Nebraska is the center of the ever widening area in which Kochia is becoming a serious hay fever menace. At North Platte, three fourths of the Chenopod-Amaranth pollens and more than half of the total pollen count was Kochia. Late clinical reports on this pollen are not available, but the plant is rapidly becoming as important as Russian thistle.

Russian thistle is more widely distributed than Kochia. The eastern edge of its territory is a line from the Panhandle of Texas to the northwest corner of Minnesota. This is a region in which the territories of Russian thistle and ragweed overlap. At Pierre, S. D., there was about half as much Russian thistle pollen as ragweed pollen. While Russian thistle must be regarded as a regional hay fever menace, the plants may be found in all parts of the country wherever conditions are favorable. It is, of course, crowded out of soil that will support a normal growth of other weeds—especially the larger ragweeds—but in sandy areas and on railway embankments composed of cinders, and sometimes in riprap on river levees, it gains a small foothold. Large sandy areas on the shores of Lake Michigan support a rather vigorous growth of this plant, but it is impossible to find more than an occasional pollen granule on the Chicago slides. When the plant is abundant in the immediate vicinity of a hay fever sufferer's residence, it should always be considered a potential factor.

From eastern Nebraska to central Texas is an area in which western water hemp (*Acnida tamariscina*) thrives in all moist land and is especially abundant in corn fields when the season is favorable. It is by far the best producer of any of the members of these two closely related families. Most of the enormous amount of pollen other than ragweed for the season of 1932 at Wichita, Oklahoma City and Omaha, as well as the smaller proportion at Kansas City, must be credited to this plant.

Palmer's amaranth (*Amaranthus palmeri*), which is quite as capable of producing pollen as is western water hemp, is found only in the Southwest and probably enters into this survey only at Dallas and San Antonio, Texas.

GRASS FAMILY

As noted by all botanic investigators in allergy, the grass family is composed of a great many members all of which produce toxic pollen, but few of which produce it in large amounts. The possible importance of grass during the ragweed season is greater than is indicated by the mere 4 per cent of its pollen in the general averages. Grass symptoms once started during the more or less definite season in May and June often seem to persist through July and merge indefinitely with ragweed symptoms. It is therefore worth while to give the grasses some consideration during the fall. Corn pollen has often been mentioned as a factor of restricted local importance. The extremely large corn pollen granules readily distinguishable from other grass pollens are occasionally found on the slides. Some grass pollen was found at every station at which slides were exposed, the greatest amount being recorded at Oklahoma City, but the proportion was of course small, being but 3 per cent. Proportions as high as

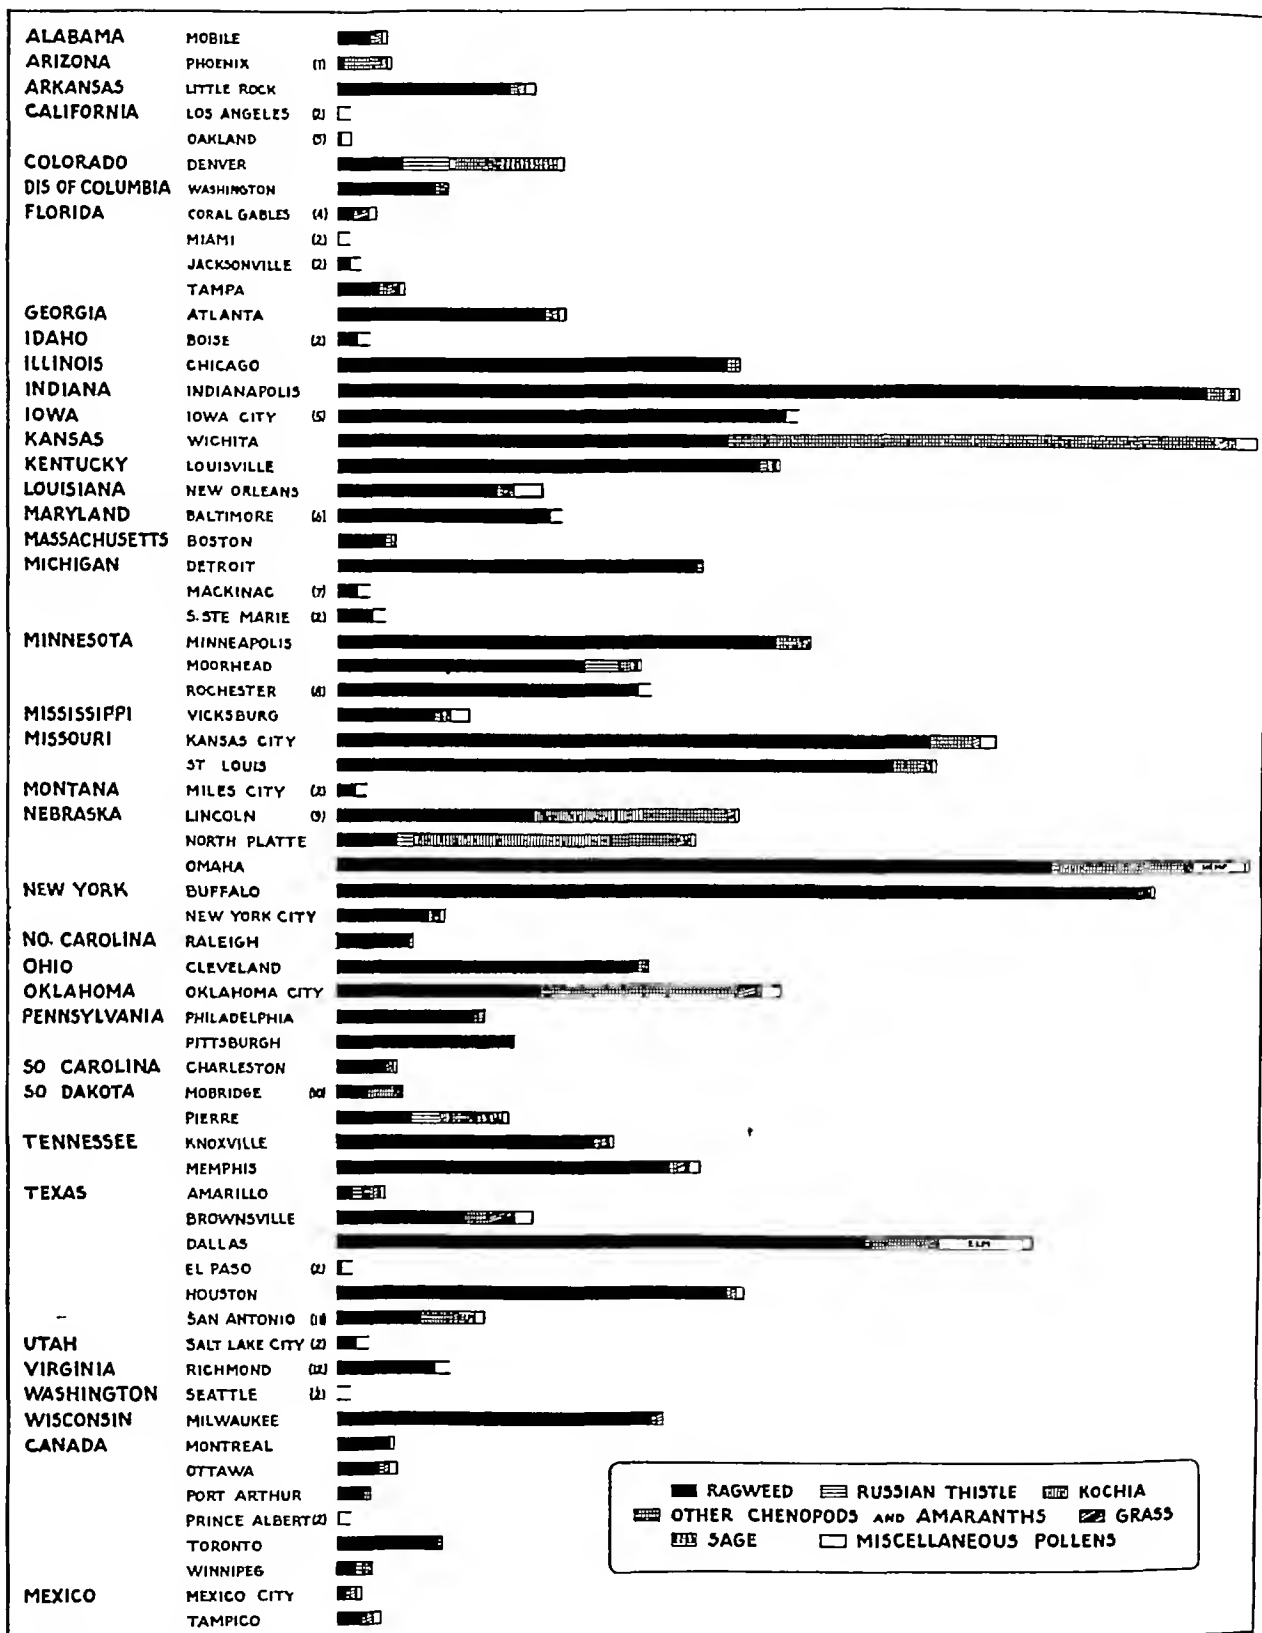

17 per cent of grass pollen are found along the southern gulf, and more at Mexico City. Since all grass pollens are similar in appearance varying only in size, it is quite impracticable to try to identify the different species of grass pollens found in the air. Some of the grasses in bloom south of the Mason and Dixon line during the ragweed season are Bermuda grass, Johnson grass and the various species of brome grass, locally known as brome, or broom sedge. From the size of the pollens found on the southern slides, I am convinced that Johnson grass contributes a greater part of the atmospheric grass pollen than has been supposed. In the North it is difficult to suggest the source of the small percentage of grass pollen. The most conspicuous of the fall-pollinating grass is the common crabgrass or lawn garden and field, but there are a number of other species that might be of slight local importance.

SAGE

The sages are closely related to ragweed and the pollens often interact on skin tests. Sage pollen is known to be very active in hay fever, but the plants are not to be compared with the ragweeds in productive ability. The prairies of the Mississippi Valley were originally covered with a number of species of these plants which have now been largely destroyed by cultivation. Traces of them may be found on such remnants of virgin prairies as railroad rights of way. No attempt is made in this paper to distinguish between the pollen of the various species of sage, of which prairie sage (*Artemisia ludoviciana*), pasture sage (*Artemisia frigida*) and sage brush (*Artemisia tridentata*) may be mentioned as examples. Annual sage (*Artemisia annua*) is a very common weed in waste places in the cities along and south of the Ohio River. About one third of the total pollen crop at Denver is from sage. This is an indication of what may be encountered throughout the Rocky Mountain region.

COMPOSITE FAMILY

In this paper, as in most discussions of hay fever pollens the ragweeds and sages while members or immediate relatives of the composite family, are classified by themselves, since practically all other composites are insect pollinated and hence of slight or no importance in hay fever. The deep-rooted tradition connected with goldenrod is perpetuated by its wide and showy distribution as well as by the fact that its pollen usually gives positive skin tests when applied to ragweed patients. It is still discussed as a hay fever possibility in spite of the scarcity of its pollen and all proofs of its almost complete absence from the air. In this study diligent effort was made to record all composite pollen granules. A few were encountered on the slides from almost every station and it will be noted that the season for them is uniformly late. It is significant that they usually appear on the slides in clumps, so that the statistics for this group of pollens cannot be regarded in quite the same light as those for other pollens whose presence in the air is usually in single granules. In some cases, almost the entire amount found at a station appeared in one large clump. The greatest amount was found at New Orleans where the proportion was 13 per cent of the total pollen count. The amounts and proportions were somewhat larger along the Gulf than farther north. Most of this composite pollen is not from goldenrod. I am certain. Of its true source, I cannot be sure. That found in the South may be from the widely distributed plant locally known as dog fennel.

Proportion of the various pollens found on atmospheric slides exposed during the fall of 1932 except as noted. 1 Unpublished data (1928-1929) cooperation of Dr Orville Harry Brown. 2 Ragweed data only for year 1929 except Jacksonville Salt Lake City Prince Albert (1930) Durham O C. That found in the South may be from the widely distributed plant locally known as dog fennel.

(*Eupatorium capillifolium*), from horse weed (*Erigeron canadensis*), from false wormwood (*Parthenium hysterophorus*) or from sneeze weed (*Helenium autumnale*). In the North at this season there are, besides horse weed, numerous species of aster and goldenrod. This group of plants is not very important, either locally or generally.

ELM

In a previous paper⁵ covering clinical and botanic experiences for two seasons at Dallas, the unusual situation was noted of a tree pollen seriously interfering with ragweed pollen therapy. Records are now available for four successive seasons, not only at Dallas but in the surrounding areas. In 1932, as in 1929, there was an acute elm shower centering at Dallas and lasting for about ten days. Slides exposed in 1929 at Mineral Wells, Texas, some 60 miles west of Dallas, show that the elm was as common there as at Dallas. San Antonio records show considerable elm pollen. Some elm pollen was found at Memphis, Tenn., Vicksburg, Miss., Oklahoma City and Little Rock, Ark. As stated,⁵ this pollen is from one species of elm (*Ulmus crassifolia*). East of the Mississippi River there occurs another species of fall-pollinating elm (*Ulmus serotina*), which as yet has not proved to be of any practical importance. Occasional granules of elm pollen are encountered during the fall north of the Mason and Dixon line, where it is known that none of these species exist. There is no question but that these pollens are carried out of the South on high southwest winds at the time of the Texas elm season. It may be added that during 1930 and 1931, when rainfall was very much restricted in central Texas, there was no acute elm season and the total amount of the pollen found on the slides was very small. This is, then, a local (if the large area of central and eastern Texas may be considered local) factor to be reckoned with only in favorable seasons.

HEMP

While hemp (*Cannabis sativa*) belongs to a family that is closely related to the fall-blooming elms of the South, it is as yet of only local distribution and importance. At various places along the Missouri River, as well as along the Mississippi River, there are areas in which hemp is more common than giant ragweed, but Omaha is the only locality investigated in this study in which the plant assumes allergic importance. There is ample clinical evidence of its importance in hay fever,⁶ both as a complicating and as a specific factor in Omaha. There are probably other localities in which the plant is prevalent enough to be taken into consideration in hay fever work.

SUMMARY

The hay fever plants of sufficient distribution to be considered complicating factors in ragweed hay fever are hemp, Palmer's amaranth, Russian thistle, Kochia and the various species of sage.

They are largely confined to the area between the Mississippi River and the Rocky Mountains.

Fall-pollinating grasses are of some importance in the Gulf region and of possible importance farther north.

During favorable seasons in central Texas, elm pollen is of clinical importance.

Hemp is an interesting local hay fever plant at Omaha.

THE DIAGNOSIS AND TREATMENT OF
ADDISON'S DISEASE

GEORGE A. HARROP, M.D.

ALBERT WEINSTEIN, M.D.

LOUIS J. SOFFER, M.D.

AND

J. H. TRESCHER, M.D.

BALTIMORE

During the past two and one-half years we have treated thirteen cases of Addison's disease by means of the suprarenal cortical extract made according to the method of Swingle and Pfiffner. The diagnosis of each of these cases we have regarded as unequivocal. We have had seven deaths (table 1), and six of our patients are now living (table 2). All of the seven fatal cases have come to autopsy, and the clinical diagnosis of Addison's disease has in each been proved correct. Four were due to cortical atrophy. Of the three due to tuberculosis, case 1 (table 1) was the first one in which treatment was given, and in the light of our later experience, adequate amounts of extract were not administered. The other two patients had advanced tuberculous lesions elsewhere in the body which probably caused death. An earlier report appeared in THE JOURNAL a year ago.¹

We have been greatly puzzled for some time as to the cause of our poorer results, compared to those reported by others, in the use of the cortical hormone in treatment. Our extract has an assay value, when tested on suprarenalectomized dogs, practically equal to that prepared in the Princeton Laboratory and higher than specimens of commercial preparations that we have examined. Indeed, the material that we used during 1930-1931 was made under the direction of Dr. Pfiffner at Princeton. A considerable number of patients have been referred to us for treatment during the last three years in whom, on one ground or another, it has been possible to rule out the presence of Addison's disease. We have come to the conclusion, therefore, that the question of diagnosis may enter into the explanation of our poorer results from this form of therapy. Patients with doubtful pigmentation, loss of weight, fatigability, weakness and hypotension often cause difficulty. Elsewhere we have advanced the view, based on our studies on the suprarenalectomized dog, that certain phenomena, namely, continued hypotension during the remissions, hypoglycemia, and the pigmentation, are associated primarily with lesions of the suprarenal medulla, whereas those seen during the relapse, namely, the marked asthenia, the gastro-intestinal symptoms and the group of phenomena associated with the shock and concentration of the blood so typically seen, are due to deficiency in the cortex. It has been often observed that the duration of life is longer and the severe crises are less frequent in patients in whom pigmentation is an outstanding characteristic, and in whom asthenia and gastro-intestinal symptoms are less marked.

We submit our criteria for clinical diagnosis and, in addition, propose a method for the differentiation of Addison's disease from other conditions that simulate it.

PIGMENTATION

Definite pigmentation of the skin or mucous membranes is an indispensable sign on which to make the

1 Harrop, G. A., Jr. and Weinstein, Albert. Addison's Disease Treated with Suprarenal Cortical Hormone. (Swingle-Pfiffner). *J. A. M. A.* 98: 1525 (April 30) 1932.

diagnosis with assurance. The pigmentation of the mucous membranes in the mouth and on the upper and under surfaces of the tongue is particularly characteristic. When pigmentation does not occur, the clinical diagnosis is questionable and cannot be made with confidence.

A lessening of the degree of the pigmentation has been observed in patients under treatment. This change takes place over a considerable period of time, usually many weeks. We have never observed the dramatic improvements occurring over night which have been reported.

Prof. Max Brödel and his staff have assisted us in the study of the color changes that are observed and have made paintings of selected areas of the skin at various intervals during treatment. When one compares a series of these paintings, it is possible to note the alterations that have occurred. The changes are rather characteristic and consist first in an increase in the proportion of pink in the skin and later in a gradual lightening of the brown component. These changes

TUBERCULOSIS

Since from 70 to 80 per cent of the cases of Addison's disease are said to be associated with tuberculosis of the suprarenal glands, an attempt to locate evidence of associated tuberculosis is always made. Only two patients in this group had evidences of active tuberculosis. One had active pleuritis, the other tuberculous osteomyelitis and pleuritis. The use of skin tests with old tuberculin is of some value when there is a marked reaction following injections of high dilutions, from 0.001 to 0.0001 mg. In addition, an attempt is always made to demonstrate calcification in the suprarenal glands by means of the x-rays. This procedure is to be viewed with caution because calcified lymph glands may lie in this region, as do areas of calcification in the rib cartilages that overlie the suprarenals in the roentgenogram. Only in one case have we felt reasonably certain of the presence of calcification in the suprarenals.

It is to be recalled that from 10 to 15 per cent of all cases of Addison's disease are associated with atrophy of the suprarenal cortex. Although this pathologic

TABLE 1—Cases of Addison's Disease Treated with Suprarenal Cortical Hormone with Fatal Outcome

Case	Patient	Age	Sex*	Duration of Illness Before Treatment	Duration of Treatment	Number of Relapses	Blood Pressure Change	Gain in Weight	Autopsy Diagnosis

are never rapid and are due to two factors: the cessation of excessive deposits of pigment and a mechanical wearing away of the outer layer of the skin in which the pigments have been deposited. This method of study of the pigmentation has proved useful, because one frequently gains the impression that the color is lighter, when an inspection of the drawings shows that no definite change is to be detected.

BLOOD PRESSURE

The blood pressure is usually low, and all but one patient in this group, at some time, had a systolic blood pressure below 90 mm of mercury. The blood pressure is described as falling rapidly when the subject assumes an upright posture. This fall in pressure is said to be associated with a decrease in the pulse pressure, a rise in the pulse rate, and syncope. This type of reaction has been seen in only three patients and disappeared later as their general condition improved. This response is not dissimilar to that seen in many patients suffering from chronic debilitating disease and no doubt is the explanation for the syncope that occurs when these people try to get up and go about their usual activities.

state is quite different from the more common caseous tuberculosis of the suprarenals, the clinical manifestations of the disease are indistinguishable. As a case in point, one of the patients (R. M. C.) had both a brother and a sister who died of pulmonary tuberculosis. As a child, she had cervical glands that drained for some months. We were very suspicious of tuberculosis as the etiologic agent. However, when the case came to autopsy a most striking degree of cortical atrophy was found. Evidences suggestive of tuberculosis elsewhere, therefore, do not definitely prove its presence as the etiologic agent.

DEXTOSE TOLERANCE AND SENSITIVITY TO INSULIN

The tolerance to ingested dextrose is generally described as being increased in patients with Addison's disease. However, only one patient in this group showed a striking abnormality. A low fasting blood sugar is often found. In the literature are references to the occurrence of hypoglycemia following the ingestion of dextrose. Systemic reactions are described, associated with lowering of the blood sugar. We noted this in our earlier paper.¹ Because suprarenalectomized

animals are extremely sensitive to insulin and because some of the reactions occurring clinically in the acute relapses resemble those seen in hypoglycemia, an effort was made to see if the effect of small injections of insulin might be made the basis of a reliable diagnostic procedure. The method employed consisted in the intravenous injection of 2 units of insulin and the determination of the blood sugar at frequent intervals. Three of the patients studied had an unusual degree of hypoglycemia during this procedure. It is to be remembered that patients with untreated myxedema, and many with hypophyseal dysfunction as well as certain undernourished persons, are particularly sensitive to insulin. The test has, then, no certain diagnostic significance.

ASTHENIA AND MUSCULAR WEAKNESS

Weakness has been striking, and all the patients have been unable to carry on their ordinary activities. The fact that only one patient was anemic is in contrast to the emphasis placed on this sign by Addison in the original description of this syndrome. The pulse, while feeble, is not usually slowed, neither is the body temperature lowered, as a rule, unless the patient is in relapse. However, the general inanition is reflected in the basal metabolic rate, which is commonly low, the average value for the group being —18 per cent. Numbness and tingling in the extremities and pain in the back and thighs are frequent complaints. We regard a history of muscular weakness and fatigability as of prime importance.

GASTRO-INTESTINAL SYMPTOMS

The appetite is usually poor, and, as the disease progresses, periods of nausea become a striking feature. Loss of weight is conspicuous. The average weight loss for this group was 30 pounds (13.6 Kg). Vomiting and diarrhea are frequently seen during the course of an acute relapse. Nausea and vomiting should place one on his guard as to the possibility of an impending crisis.

THYROID MEDICATION

The acute crises that occur during the course of Addison's disease are precipitated frequently by infections, undue exertion, or drugs, such as thyroid extract, which increase the basal metabolic rate. The sensitivity to thyroid extract was impressed on us when we administered the material to two patients in order to raise the very low basal metabolic rates that were present. In each instance, a relapse was precipitated.

We have come to the conclusion that absolute diagnosis on the basis of any one of the criteria which we have discussed is not possible, and we are inclined to believe that it cannot be made with confidence unless there is definite and characteristic pigmentation, associated with at least one or two of the other features mentioned.

USE OF SALT-FREE DIET AS DIAGNOSTIC PROCEDURE

We now wish to propose an additional diagnostic test, based on our animal experiments during the past two years. It has been known for some time that suprarenalectomized dogs that receive injections of sodium chloride survive longer than animals not so treated. Observers have not been wanting who have pointed out that animals dying after removal of the suprarenal glands are in a condition of shock, as evidenced by marked hypotension, lowered body temperature, cardiac failure and hemoconcentration. Unfortunately, the fatal outcome of bilateral suprarenalectomy within a

few days has rendered it impossible to decide with certainty whether the observed condition of shock was due to removal of the suprarenals alone, or whether a decisive role might not be played by the effects of the major surgical procedure or of the anesthesia. Studies made with the aid of the cortical extract indicate definitely that animals with well healed wounds, and maintained in good condition, when thrown into a state of insufficiency by the withdrawal of the injections of extract show a typical course characterized by gradual hemoconcentration (increased blood oxygen capacity, erythrocyte count and volume of packed red cells), a rise in nonprotein nitrogen and in plasma proteins, in the later stages, a fall in blood pressure, basal oxygen consumption and blood flow, and lowered bodily temperature and circulatory collapse.² On readministration of the extract, this cycle is reversed and the animal is restored to his previous good condition, thus proving that the symptoms were due solely to withdrawal of the extract.

Accompanying the hemoconcentration, which we regard as the primary event in the train of symptoms that we have just described, there is a fall in total plasma base, plasma chlorides and sodium, while a marked increase occurs in the urinary output of sodium and chloride. The volume of urine excreted is maintained until within a few hours of death. The conclusion is drawn, that the hormone exercises a regulatory influence over the excretion of water, sodium and chloride, and that when this regulation is removed the kidneys waste these components, not alone from the blood plasma, but in even greater amounts from the extravascular tissue fluids. The resulting dehydration is, then, responsible for the symptoms and death from suprarenal insufficiency following withdrawal of the extract. If the regulatory influence over the excretion of sodium and chloride is lost after the injections of the extract have been stopped, it would appear likely that the animal, after the withdrawal of the extract, when it was placed on a salt-poor diet, would go into insufficiency much more rapidly than when the salt intake was normal. Conversely, an animal on a high salt intake should have a much lower maintenance requirement for extract than an animal on a normal salt intake. Such we have found to be the case.² Furthermore, animals on a bare maintenance dosage of extract, when placed on a salt-free diet, will show the characteristic clinical, physiologic and chemical evidences of insufficiency, and if they are not allowed to sink too deeply into shock they may recover after the administration of sodium chloride alone.

At the beginning of this study, we kept all of our patients on daily injections of the cortical hormone. They administered the material to themselves by hypodermic injections. However, in June, 1932, three patients were doing exceedingly well on a supply of cortical hormone which later proved to be of no value in keeping suprarenalectomized dogs alive. It therefore seemed important to determine whether or not daily injections of the hormone were necessary for the well being of the patients. Having assured ourselves that the patients were under very close medical supervision, we sent extract of low potency to them but at the same

time prescribed a diet high in salt. They have been watched for the past nine months under such conditions and, during that time, have continued to gain weight and strength. It is also true that one patient who was under observation in this hospital began to show signs of relapse six weeks after the injections of cortical hormone had been replaced by hypodermic injections of sterile water. Improvement was again noted following the resumption of the injections of potent material. Since that time this patient has been transferred to another hospital, where, again, it is found that daily injections of the hormone are necessary for her well being. In such instances of chronic relapse, of which we have had several, continuous injections of the extract are certainly needed.

The tendency of patients with Addison's disease during the acute relapse to show hemoconcentration, reduction in plasma total base and chlorides and rise in nonprotein nitrogen has been repeatedly observed by ourselves and has recently been reported by Loeb,³ who rightly stresses the marked drop in plasma sodium. We have previously pointed out the similarity of the Addisonian crisis to the acute suprarenal insufficiency of the experimental animal. That a reaction simulating the crisis of Addison's disease may occur in a patient with Addison's disease following the withdrawal of salt from the diet and that this may prove both of diagnostic and of therapeutic importance is demonstrated by the following observations.

CASE 1—A man, aged 21, white, unmarried, noted a lack of endurance two years before. This was followed six months later by a striking increase in skin pigmentation. Physical examination a year before admission revealed characteristic generalized pigmentation of the skin, the buccal mucous membranes and the tongue. There was evidence of recent loss of weight. The blood pressure was 90 systolic, 60 diastolic. There was a positive skin reaction to 0.001 mg of old tuberculin. X-rays revealed calcification in the suprarenals. He was placed on daily injections of the cortical hormone and, over a period of one year, has gained strength and weight (44 Kg.). He was one of the three patients previously mentioned who had received extract of low potency.

When admitted to the hospital for the present study he had no complaints. His physical condition was essentially the same as it was the previous year. He was able to take long walks and do light work. After a preliminary control period, and blood examination, salt was withdrawn from the diet, and fluids were forced to 3 liters a day. Two days later he lost his appetite and began to complain of great weakness. During the afternoon of the fourth day of this low salt diet a second sample of blood was examined with the striking changes in plasma total base, sodium and chlorides noted in table 3. At this time the patient was nauseated and had vomited small amounts, the blood pressure had fallen slightly, and the body temperature was lowered. The picture was clearly that of a relapse. Salt was at once added to the diet but the condition of the patient did not improve, and five hours later saline solution was given intravenously. Since he did not respond promptly, large amounts of extract also were administered both intravenously and subcutaneously. Twenty-four hours later he felt much better, and from then on improvement continued rapidly. The plasma electrolyte pattern did not return to its original form as rapidly as did the evidence of clinical improvement, but it was essentially normal eighteen days later. Studies of intake and output on this patient during the three full days that he was on the low salt diet showed a total chloride intake of 30.6 milliequivalents and an output during the same period of 26.4. During the ten hours preceding the taking of the blood sample, when the plasma chloride concentration was 81.2 milliequivalents per liter the urinary chloride excretion

amounted to 40 milliequivalents. When it is recalled that Ambard considered the normal renal threshold for chlorides to be 96 milliequivalents per liter it will be seen that this low threshold for the excretion of chlorides is quite unusual. The kidney appears to be unable to prevent the excretion of sodium and chloride, and the loss of these ions relative to the sodium chloride intake therefore becomes very large.

CASE 2—A woman, aged 61, noted increased pigmentation of the skin five years earlier. Two years before admission she became acutely ill with nausea, vomiting and weakness and lost 37 pounds (168 Kg.) within six months. Examination six months later showed characteristic pigmentation of the skin and mucous membranes. The blood pressure was 94 systolic, 68 diastolic. During the period of our observation, which has extended over nineteen months, she administered to herself daily injections of the cortical extract. The extract that she received last spring was of the same low potency as that administered to patient 1, but she has continued to feel well.

At the time of hospital admission she felt exceedingly well. The blood pressure was at the normal level (120 systolic, 70 diastolic), and had been at this level for the preceding six months. There had been an excellent gain in weight (9.4 Kg.), and the patient was able to carry on all of her usual activities. Following a control period on a weighed diet, salt was withdrawn but fluids were forced. Forty-eight hours later she felt weak and shaky and almost fainted when she tried to walk. The appetite was good, however. The following day, she felt

Felt very well and discharged from hospital						

weaker and remained in bed. There was a sharp decline in the intake of food. On the morning of the fifth day she was completely exhausted, was irritable and refused all food. She was nauseated but did not vomit. The blood pressure was lowered (100 systolic, 50 diastolic), and the pulse rate was somewhat elevated. The picture was obviously that of an early acute relapse. The changes in the blood electrolyte structure are shown in table 4. Salt was accordingly added to the diet in large amounts but none was given by vein and no cortical extract was administered. Within the next thirty-six hours she commenced to eat again and felt much better both physically and mentally. Following this, there was a rapid return of appetite and muscular strength.

The production of typical symptoms of the Addisonian crisis with the usual changes in the chemical constituents of the blood of these two patients, and with relief of symptoms without the use of hormone in one case, merely by restoration of salt to the diet, clearly indicates the important role played by sodium chloride and its paramount value in the treatment of the acute relapse.

By way of contrast, the effect on the plasma electrolytes and on the urinary excretion of sodium and chloride of a normal person is shown, following the use of such a salt-free diet.

CASE 3—A man, aged 35, was transferred to the metabolism ward following an uneventful recovery from the surgical repair of an indirect inguinal hernia. There were no complaints and the physical examination showed nothing abnormal. After a

³ Loeb, R. F. Chemical Changes in the Blood in Addison's Disease. *Science* 78: 420 (Nov. 4) 1932. Effect of Sodium Chloride in Treatment of a Patient with Addison's Disease. *Proc. Soc. Exper. Biol. Med.* 30: 808 (March) 1933.

preliminary period of observation, he was placed on a salt-free weighed diet for ten days, which he ate with good appetite. The studies of the blood were made prior to the institution of this diet, and on the sixth day and on the tenth day of this regimen. No untoward symptoms were noted throughout the period of observation (table 5). In contrast to the marked changes in the plasma electrolytes noted in the patients with Addison's disease, no changes were noted over a period twice as long in this normal individual, when on a similar diet very low in salt.

While the effect of salt deprivation is thus shown to be of diagnostic value in outspoken cases, the negative

He had noted these during the preceding two months. A few weeks later he developed several furuncles on the legs. Areas of dark brown pigmentation were deposited around these lesions which persisted for weeks. The blood pressure, which was 90 systolic, 30 diastolic on admission, gradually rose to a level of 120/80, and he became active and felt well.

Further studies revealed roentgen evidence of thickened pleura at the left apex. A marked skin reaction to 0.1 cc. of 0.001 mg. of old tuberculin was noted. There was no evidence of calcification in the suprarenals. The basal metabolic rate was -5 per cent. There was hypoglycemia associated with characteristic symptoms three hours after the ingestion of

result obtained in another patient in whom Addison's disease was suspected is of interest.

CASE 4—A man, aged 55, white, complained of a cough and sore throat of three days' duration. There had been some blood-stained sputum and mild chills. The appetite had remained good. Fifteen years before he had been a patient in a tuberculosis sanatorium for fifteen months. A daughter had died of pulmonary tuberculosis. During his stay at the sanatorium the blood pressure was noted to be 114 systolic, 80 diastolic, but periodic health examinations since that time had shown the blood pressure to be low.

On admission he was found to be acutely ill with a temperature of 103.4 F and considerable prostration. The temperature fell abruptly twenty-four hours later. It was thought that he had influenza and bronchopneumonia (Pneumococcus type VIII was isolated from the sputum, no acid-fast bacilli were demonstrated). The convalescence was rather prolonged. There was a slight increase in the depth of the skin pigment, but most noteworthy was the presence of many jet black patches of pigmentation on the lips and buccal mucous membranes.

The patient showed a normal response to the insulin tolerance test. There were no striking changes in the blood pressure following alterations in posture. The urine never showed pathologic changes, and tests of the kidney function were all within normal limits.

The patient ate with great relish a salt-free diet for twelve days, during which time he increased in strength and gained 4½ pounds (2 Kg). The response was exactly that of the normal person (case 3). No noteworthy change was observed in the plasma electrolyte pattern, and the sodium and chloride urinary output dropped promptly, to spare these constituents when the salt intake was restricted. Because the evidence of suprarenal insufficiency was not conclusive, he has not been given the cortical hormone and is not included in this present series of cases. He has remained well to date.

We feel that, in the last case cited, the pigmentation is quite characteristic of Addison's disease, and the long standing hypotension and definite association with tuberculosis is noteworthy. Elsewhere, we have

commented on the likelihood that pigmentation and hypotension may be due primarily to disease of the suprarenal medulla rather than to that of the suprarenal cortex. Tuberculous lesions usually first attack the medullary portion of the gland, and it is possible that such may be the case here and that the cortex is not as yet vitally affected. The patient has never suffered from what we regard as true symptoms of cortical insufficiency—hemoconcentration, grave asthenia, severe gastro-intestinal symptoms and "shock." On the other hand, had this patient been treated from the first with cortical hormone, the great improvement which he has shown, since recovery from influenza, might well have been erroneously ascribed to the use of the extract.

We believe that the use of a salt-free diet is of definite diagnostic value in determining the presence of Addison's disease, and especially in indicating the danger of relapse. It may be in this condition of practical use in determining the patient's requirements for treatment by cortical extract. We should hesitate to use it, however, without the closest medical supervision and without cortical extract at hand for emergency use. The importance of a liberal salt intake for patients with Addison's disease seems obvious.

TREATMENT WITH HIGH-SALT DIET

We have now four patients under study who are receiving diets high in salt content. They receive, in addition, from 1 to 6 Gm of sodium chloride in capsules, daily, but are being given no injections of the cortical extract. All of this particular group state that they feel stronger and tire less easily than at any time since coming under our observation. Two, who had previously suffered from persistent recurring nausea, and occasional attacks of vomiting, even while receiving daily injections of the cortical hormone, are now practically free of these symptoms. The weight gain in one patient is quite definite in contrast to his failure to gain when on previous treatment with the cortical extract alone. We avoid the administration of salt in such quantities as to cause subcutaneous edema, although there would seem to be no particular harm in this from the standpoint of the disease itself. The production of diarrhea or of nausea from the use of salt must also be avoided. Patients with gastro-intestinal symptoms tend to show lowered plasma total base and plasma sodium concentrations, and these are raised, when present, to more nearly normal levels on the high salt regimen. When the nonprotein nitrogen (or urea) concentration is elevated, the plasma chloride level is usually lowered, and these abnormalities are also affected by the higher salt intake. We use the changes in these plasma electrolyte values as one guide to the amount of salt required in treatment. When salt alone does not restore the proper plasma electrolyte levels, cortical extract should also be employed.

During the remissions of the disease we insist on patients avoiding undue exertion and protecting themselves against exposure to infection. We recommend diets as high in caloric value as possible, liberally salted, and, if necessary, we give several grams of additional salt in capsule form. In addition, we advise the use of from 1 to 3 ounces (30 to 90 cc) of cottonseed oil daily. The latter treatment is based on the fact that the dosage of cortical hormone required to maintain suprarenalectomized dogs in a normal state is materially lowered when cottonseed oil is given simultaneously. It increases the caloric intake and is usually well tolerated. In the treatment of the acute relapse, we

stress as previously¹ the great importance of early diagnosis and the prompt vigorous treatment with salt by mouth or physiologic solution of sodium chloride and dextrose solution intravenously, and the use of large amounts of cortical extract.

CONCLUSIONS REGARDING HORMONE THERAPY

We believe that the clinical value of injections of the cortical hormone as a routine treatment during the remissions of Addison's disease has not been satisfactorily demonstrated. So far as our experience indicates, however, there is no danger whatever in the use of extract if this seems desirable. We would stress again the fact that we have never seen any untoward or toxic effects as a result of the treatment by cortical extract although we have used it in many types of patients, some of whom have received very large doses both subcutaneously and by vein. We do not doubt, however, that faulty preparation may lead to dangerous consequences. The extract has no definite effect on hypotension or on the pigmentation. We are not convinced that it has any effect on nutrition and weight. The chief value of the cortical extract lies in the treatment of the relapse, the symptoms of which we regard as fundamentally those of shock, and due primarily to cortical deficiency. In patients showing such symptoms for longer or shorter periods injections of the cortical hormone extracts are of definite value and may be of vital importance.

BRUCELLA (ALCALIGENES) INFECTIONS IN MAN

THE INTRADERMAL REACTION AS AN AID IN DIAGNOSIS

H. C. YECKEL, M.D.

AND

O. D. CHAPMAN, M.D.

SYRACUSE, N. Y.

Our object in this study was to ascertain, if possible, the value of the intradermal test as an aid in the diagnosis of undulant fever as it occurs in this locality.

Since the pioneer studies of Fleischer and Meyer¹ in 1918 and Burnet² in 1922, a number of workers have studied this reaction, some using bacterial extracts or filtrates similar to Burnet's "melitin," others using killed bacterial suspensions, the two groups agreeing as to a high percentage of positive results in definite infection but disagreeing somewhat concerning so-called false positives. Leavell and Amoss³ give a very good analysis of this work and state that "the specificity of the tests has been the subject of the greatest contention. The consensus seems to be that the bacterial suspension gives fewer false positive reactions than the filtrate. In fact, only a few false positive reactions with the suspension have been reported." Levin⁴ used a fat free abortus protein prepared by extracting the abortus organism with alcohol and ether similar to the method

From the Department of Medicine and from the Department of Bacteriology, Hygiene and Sanitation, Syracuse University College of Medicine.

⁴ Levin, William. The Intradermal Test as an Aid in the Diagnosis of Undulant Fever. *J. Lab. & Clin. Med.* 16: 275 (Dec.) 1930.

used by Fleischner and Meyer¹ with good results. Leavell and Amoss³ used both suspensions and extracts with the result that they concluded that "heat killed suspensions seem to have more specific action than bacterial filtrates."

Following the suggestions of Giordano,⁵ we have used the killed bacterial suspensions

PROCEDURE

Brucella (*Alcaligenes*) *abortus* strain 80 obtained from Carpenter in 1927 was grown on beef infusion agar slants for forty-eight hours and emulsified in physiologic solution of sodium chloride. This suspension was then killed by heat (60 C for sixty minutes), properly controlled, sufficient phenol added to bring the final concentration to 0.5 per cent and then diluted with 0.5 per cent phenolized physiologic solution of sodium chloride to the density of barium sulphate standard I. One-tenth milliliter of this phenolized heat killed bacterial suspension was injected intradermally in the test

INTERPRETATION OF REACTIONS

Contrary to previous observers we feel that the optimum time to read the result of the intradermal test is on the fourth day, approximately ninety-six hours after the injection.

We find that the false positive reaction (nonspecific) begins as a small circumscribed area of redness at the site of injection at about twenty-four hours and disappears within the next twenty-four hours so that at the end of forty-eight hours very little evidence remains. At approximately this time the truly positive reaction begins to show redness and slight induration, increasing so that by the fourth day the area is about 5 cm in diameter, is elevated about 1 cm, is tender and shows some local heat. Usually there is no general evidence of unusual fever or malaise. The area remains in this condition, showing very little change, for about seven to fourteen days, except that the tenderness gradually subsides. The redness and swelling then gradually recede and by the end of the fourth week there remains a residue of slightly brownish discoloration or pigmentation which is not tender to the touch. In a few cases there appeared to be a redness which extended up the arm in streaks similar to a lymphangitis, but suppuration or necrosis did not occur. These positive reactions were very uniform in their time of appearance, their intensity (redness, elevation and induration) and their time of recession. We have had but one case that manifested a generalized reaction with fever, malaise and a skin eruption (erythema brucellum) on the fourth day.

There was one other type of reaction which might be classed as slightly positive by some observers. This reaction resembled a true positive with the exception that it usually appeared on the second day, as an area of redness smaller in size, with practically no elevation, induration or tenderness, and began to recede at about the seventh day, so that by the tenth to the twelfth day it had completely disappeared. This reaction was particularly manifest in those cases of syphilis under intensive antisyphilitic treatment. We do not feel that this reaction is indicative of brucella infection.

We performed 250 intradermal tests using this antigen. In the first 150 tests, two antigens were used, the *abortus* antigen described and a *melitensis* antigen prepared in a like manner from *Brucella melitensis* 451. As practically no difference was found in the results

obtained with these two antigens, the *melitensis* antigen was discontinued.

Fourteen (5.6 per cent) of these tests were read as definite positives. Eight (3.2 per cent) of these tests were read as pseudopositives. Two hundred and twenty-eight (91.2 per cent) of these tests were read as negatives. This group included the following list of diagnoses:

Typhoid	Carcinoma of stomach, pelvis
Scarlet fever	Diabetes mellitus
Diphtheria	Marked secondary anemia
Tuberculosis	Primary anemia
Syphilis (treated and untreated)	Cholecystitis
Gonococcal vaginitis	Cholelithiasis
Follicular tonsillitis	Cardiac disease
Pyelitis (colon bacillus)	Chronic nephritis
Arthritis	Arteriosclerotic disease
Septicemia	Hodgkin's disease
Staphylococcus aureus	Bronchial asthma
Streptococcus hemolyticus	
Streptococcus viridans	
Pyocyanus	

It might be emphasized that none of the patients were disturbed by the positive tests. The use of a strain of brucella, such as *abortus* 80, might be recommended for such intradermal tests, because it has been on laboratory medium for approximately ten years and undoubtedly has lost some of its toxicity. If a freshly isolated strain were used, one might obtain such alarming reactions as to disturb both the patient and the clinician.

COMMENT

It is interesting to note that of all the positive reactions there was only one case that did not show a possible undulant fever history or source of infection. This patient was suffering from an orthopedic condition and nothing in his history would suggest undulant fever.

Two other cases are of interest. One, a man who gave a history of malaria, but during this illness he had no periodic chills but did have excessive sweating. The other, a woman with a history of typhoid. This illness was also characterized by excessive sweating. In both of these cases the history was obtained without asking leading questions.

SUMMARY AND CONCLUSIONS

- 1 The intradermal reaction is a definite aid in the diagnosis of brucella infection in man.
- 2 The test is harmless and does not disturb the patient.
- 3 Negative agglutination and intradermal reactions definitely exclude clinical undulant fever.
- 4 The skin remains sensitive to the specific antigen long after the active infection.
- 5 In the presence of a negative agglutination reaction, the intradermal reaction may be positive and thus lead to a definite diagnosis.
- 6 *Brucella abortus* 80 is a good antigen to use for the intradermal test. It is not necessary to make a series of tests using two or more antigens.
- 7 For proper interpretation, the result must be read at approximately the ninety-sixth hour.
- 8 The nonspecific reactions usually appear within the first twenty-four or forty-eight hours and disappear by the seventy-second or ninety-sixth.
- 9 A positive reaction may mean a former infection.

Medical Arts Building

STREPTOCOCCIC SEPSIS COMPLICATING
RECOVERY FROM PNEUMOCOCCIC
PNEUMONIA

REPORT OF THREE CASES

JOHN W PARSONS, M.D.

PHILADELPHIA

AND

WALTER K MYERS, M.D.

BOSTON

Severe streptococcic infections are known to follow pneumococcic pneumonia with considerable frequency. Soon after the differentiation between pneumococci and streptococci and the recognition of the former as the principal etiologic agent in lobar pneumonia, Jaccoud¹ demonstrated that streptococci may be found as secondary invaders, causing purulent complications. Netter² mentions streptococcic septicemia as a fatal complication during convalescence from lobar pneumonia. Cole and MacCallum,³ Cumming, Spruit and Aten⁴ and Clendening⁵ found streptococcic infections to be relatively frequent during convalescence from lobar pneumonia in the army base hospitals. More recently, Avery, Chickering, Cole and Dochez,⁶ Johnston and Morgan,⁷ Cole,⁸ Suthiff and Finland⁹ and others have noted occasional cases in which the hemolytic streptococcus was the cause of fatal complications during lobar pneumonia.

The pathologic changes in the lungs of patients from whom the pneumococcus was recovered during the acute stage of lobar pneumonia but from whom the streptococcus was obtained in cultures made at autopsy have been described by MacCallum.¹⁰

REPORT OF CASES

Three cases, presenting clinical pictures similar in mode of onset, course and bacteriologic results, are reported here to call attention to the invasion of the hemolytic streptococcus leading to illness and death some days following recovery from lobar pneumonia.

CASE 1—An American-born white man, aged 30, was admitted to the hospital complaining of chills, fever and cough. He had been well until four days before entry when, following exposure to cold and dampness, he noticed general malaise, coriza and a nonproductive cough. Twenty hours before admission he was seized by a severe shaking chill, the cough became more frequent with the production of a large amount of bloody sputum and he felt a severe, stabbing pain just below the right nipple. Following the chill, the patient felt extremely ill; he perspired freely and experienced severe gripping abdominal pains associated with nausea. He vomited several times

The patient was well nourished and well developed and was obviously very ill. The face was flushed, the mucous membranes and nail beds were slightly cyanotic, and the respirations were rapid. There were paroxysms of coughing productive of a large quantity of tenacious brown sputum flecked with blood. Examination of the chest revealed the early signs of consolidation of the lower lobe of the right lung.

The following day the physical signs were those of frank consolidation of the right lower lobe and roentgen examination showed dense consolidation of that area. Sputum typing at the time of admission revealed pneumococcus type I, and specific serum therapy was instituted forty-five hours after the onset of the pneumonia. A blood culture, taken immediately prior to the administration of Felton's concentrated antibody contained pneumococcus type I and repeated cultures thereafter showed no growth.

The patient was markedly prostrated, though he improved rapidly following a critical drop in temperature on the seventh day of his illness. The temperature rose to 100 F on the ninth and tenth days. An abscess on the right arm, at the site of an intramuscular injection of caffeine sodiobenzoate was incised on the twelfth day with the evacuation of about 30 cc. of yellow pus smears of which showed gram-positive diplococci but which on culture yielded only *Bacillus welchii*. From the twelfth to the fourteenth day there were mild joint pains, which were interpreted as a manifestation of serum sickness. The patient was subjectively well for the following three days. Physical examination revealed signs of resolution over the

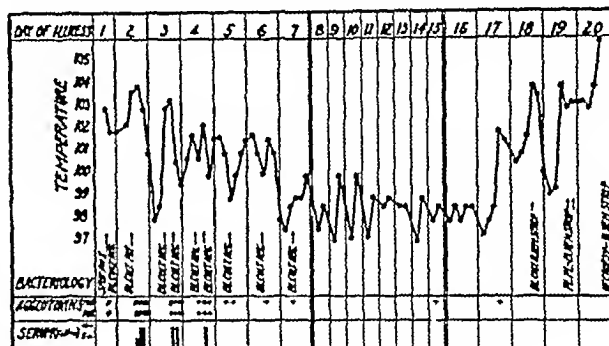

Chart 1—Course of illness in case 1

affected lobe, no evidence of fluid in the pleural cavity, and a healing incision on the right arm.

On the afternoon of the seventeenth day the temperature rose suddenly to 102 F, with corresponding elevations in the pulse and respiratory rates. The patient complained of chilly sensations, pains in the calves of the legs, and nausea. He vomited several times that day. There was an erythematous rash over the anterior wall of the chest. The following day the temperature reached 104 F, and a blood culture taken at this time revealed beta hemolytic streptococci, 12 colonies per cubic centimeter of blood.

On the morning of the nineteenth day there were signs of fluid in the right pleural cavity. Exploratory thoracentesis was productive of 10 cc of amber fluid, which showed many polymorphonuclear leukocytes and gram-positive cocci on smear. Later that day 430 cc. of similar fluid was withdrawn. Both specimens contained beta hemolytic streptococci in pure culture.

The patient sank very rapidly, and on the morning of the twentieth day his pulse became weak and too rapid to be counted accurately. He lapsed into coma and died that evening.

The urine on admission and on succeeding days showed a very slight trace of albumin. During the terminal febrile episode, in spite of adequate fluid intake, the urinary output steadily decreased in amount to a few ounces of bloody fluid that showed a high specific gravity, a heavy coagulum on boiling and numerous white and red blood cells and granular casts.

The leukocyte count was normal on admission and rose to 20,000 per cubic millimeter within a few days, but, while decreasing during the convalescent period it remained above normal. The count rose to 30,000 per cubic millimeter just before death.

The postmortem examination performed by Dr J H Peers, was limited to the contents of the thoracic cavity. The right pleura' cavity was almost completely obliterated by a layer of recent fibrinous exudate up to 4 mm in thickness posteriorly. There was no appreciable free fluid. The fibrinous exudate extended in a thin layer between the right lower and middle lobes. The right lower lobe and the posterior two thirds of the right upper lobe were solid and airless. On cut surface these portions were of a deep red with thickly scattered gray points. The right upper lobe and the left lung showed only a moderate degree of congestion. The left pleura was smooth and glistening. The pericardium contained a small amount of slightly

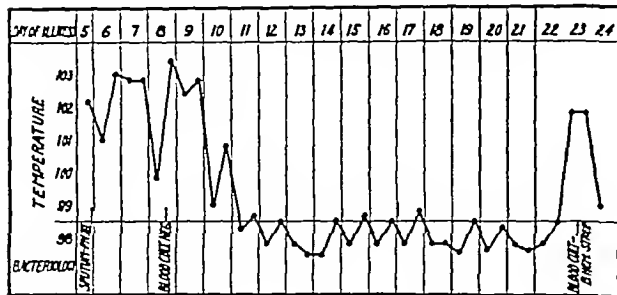

Chart 2—Course of illness in case 2

turbid fluid but no fibrin. There were numerous small subepicardial hemorrhages, most numerous over the left ventricle.

The microscopic examination of the unconsolidated portions of the lung showed very intense congestion of the interalveolar capillaries. The alveoli contained a small amount of serous exudate with a few shreds of fibrin, a few polymorphonuclear leukocytes and numerous pigment-filled monocytes. There were scattered small hemorrhages. Gram-Weigert preparations of this area showed a few gram-positive cocci in short chains in the exudate and very rarely in the interalveolar septums. The consolidated portions showed moderate congestion and hemorrhage and various stages of resolution. There were scattered areas of organization of moderate age. The overlying pleura was covered by a compact layer of fibrin. Gram-Weigert preparations of the resolving areas showed no organisms.

Beta hemolytic streptococci were recovered in pure culture from the heart's blood and from the right lung and pleura.

Summary.—A man, aged 30, entered the hospital twenty hours after the onset of lobar pneumonia. Pneumococcus type I was recovered from the sputum and blood. Serum therapy was given, with slow recovery and mild serum sickness. After ten days fever and malaise suddenly developed, and soon marked prostration with empyema of the right pleural cavity followed. Cultures of the blood and empyema fluid showed beta hemolytic streptococci. Death occurred on the twentieth day after the onset of pneumonia.

CASE 2.—A Negro, aged 60, was admitted to the hospital complaining of chills, fever, pain in the chest and a cough of four days' duration. For the preceding month he had had a persistent 'head-cold.' Four days before entry he was suddenly seized by three successive chills of approximately fifteen minutes' duration each. Shortly afterward he noticed a stabbing pain in the right side of the chest, a pain which was exaggerated by deep breathing and by a cough, which became very difficult and frequent. There was a moderate amount of yellow mucoid sputum. The pain in the chest was less severe, and the patient was subjectively improved at the time of entry.

The patient was well developed and well nourished, and was very ill. The skin was hot and moist, the tongue coated and the pharynx moderately injected. The thorax showed the physical signs of consolidation of the entire right lung, which was confirmed by roentgenologic examination. Sputum culture on the day of admission showed that pneumococcus type III was the predominating organism. Blood culture on the eighth day of illness was negative.

The patient's condition remained essentially unchanged until the eleventh day of illness when a fall in temperature and appreciable subjective improvement occurred. The temperature

remained normal during the following days and resolution of the consolidated lung progressed rapidly. The patient gained strength and was considered well on the twenty-second day of his illness. The following morning, however, there was a sudden elevation of temperature to 102 F, the pulse became soft and rapid, the patient was extremely ill. There were signs of consolidation at the base of the left lung. Beta hemolytic streptococci were obtained from blood culture. He died on the twenty-fourth day after the onset of the pneumococcal pneumonia.

The urine examinations were repeatedly negative. The leukocyte count was 15,900 per cubic millimeters on admission, fell to normal later, and rose to 36,700 per cubic millimeters the afternoon before death. The Kahn reaction was positive.

Permission for autopsy was refused.

Summary.—A Negro, aged 60, was admitted to the hospital on the fifth day after the onset of lobar pneumonia. Pneumococcus type III was obtained from the sputum. A critical fall in temperature occurred on the eleventh day of illness. Suddenly prostration and fever developed on the twenty-third day, associated with consolidation at the base of the lung opposite to that previously involved. A culture of the blood yielded beta hemolytic streptococci. Death occurred on the twenty-fourth day of illness.

CASE 3.—A housewife, aged 41, was admitted with the complaint of pain in the left lower portion of the chest. For three weeks she had been troubled with a moderately severe cough. Five days before entry she had experienced a severe shaking chill of thirty minutes' duration. This was followed by sharp and continuous pains in the thighs and lumbar region. There was a disturbing nonproductive cough. There was little change until the day before entry, when she was seized by a sharp knife-like pain in the right lower portion of the chest, which made breathing almost intolerable and was more severe on coughing.

There had been mild polyuria and nocturia during the preceding five years. She had been treated for a gastric ulcer following a moderately severe hematemesis nine years previously.

The patient was well developed and well nourished and appeared acutely ill and in considerable respiratory distress. The cheeks were flushed, the lips were dry and parched, the tongue was coated, dry and furrowed. The thoracic signs were those of consolidation of the right lower lobe of the lung and a coarse friction rub in the right axilla.

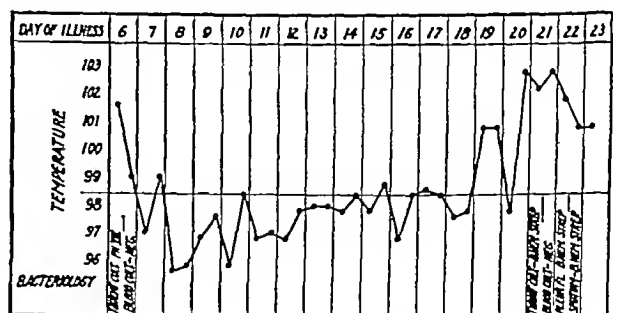

Chart 3—Course of illness in case 3

Pneumococcus type VIII¹¹ was grown on culture of the material from the pharynx. The blood culture remained sterile. The leukocyte count was 17,000 per cubic millimeter. The temperature fell by crisis the day after entry, or the seventh day of her illness, with concomitant subjective improvement. It was found that she had mild diabetes mellitus, which was easily controlled by insulin in moderate dosage.

¹¹ Cooper, Georgia, Edwards, Marguerite and Rosenstein, Carolyn. The Separation of Types Among the Pneumococci Hitherto Called Group IV and the Development of Therapeutic Antiserums for These Types, *J. Exper. Med.* 48: 461-474 (March) 1929. Cooper, Georgia, Rosenstein, Carolyn, Walter, Annabel and Peizer, Lenora. The Further Separation of Types Among the Pneumococci Hitherto Included in Group IV and the Development of Therapeutic Antisera for These Types *ibid.* 55: 531-554 (April) 1932.

For eleven days the temperature remained normal and the abnormal signs in the right lower thorax had practically disappeared, when the temperature suddenly rose to 101 F. Only a mild inflammation of the tonsils and pharynx could be detected on physical examination. The following morning, however, a severe chill was followed by a rise in temperature to over 102 F. The skin was flushed. There were signs suggesting consolidation at the base of the right lung posteriorly. The patient began to vomit. There was evidence of acidosis in the absence of hyperglycemia. The sputum was profuse and bloody, and showed beta hemolytic streptococci on culture. The signs at the base of the right lung soon became those of fluid in the pleural cavity, which were confirmed by roentgenologic examination. Fifty-five cubic centimeters of a serosanguineous fluid was obtained by thoracentesis. Cultures of this fluid showed beta hemolytic streptococci. The patient died on the twenty-third day of her illness.

Postmortem examination was not permitted.

Summary—A woman, aged 41, was admitted six days after the onset of lobar pneumonia with pneumococcus type VIII (Cooper) in the sputum. Mild diabetes mellitus existed. A critical fall in the temperature occurred on the seventh day of illness, with apparent recovery. A sudden elevation of temperature developed on the nineteenth day with signs of consolidation at the base of the right lung, followed by empyema. Beta hemolytic streptococci were recovered from the throat, sputum and empyema fluid. Death occurred on the twenty-third day of illness.

COMMENT

Case 1 was treated with Felton's concentrated antibody. The dosage was regulated by the demonstration of specific agglutinins in the patient's blood, a method described by Sabin.¹² Agglutinins against the infecting organism were found to persist after the administration of 55 cc of serum, even after the onset of the streptococcal infection. The pneumococcal infection had been very severe, and the patient had just begun to recover his strength when the fatal streptococcal infection became manifest seventeen days after the onset of pneumonia. This infection progressed rapidly to death three days later.

Cases 2 and 3 were similar in many respects to case 1. The onset of the streptococcal infection in each occurred about twelve days after the subsidence of the original pneumococcal infection and at a time when the patient's recovery seemed assured. The onset in each instance was explosive with a steadily failing course to death within a few days. Cases 1 and 3 were characterized by streptococcal pleurisy on the side of the resolving pneumonia. In case 2, consolidation of the opposite lung was found to have occurred.

The event we have described should be borne in mind in the consideration of febrile complications that occur during convalescence from lobar pneumonia caused by pneumococci. Streptococcal sepsis may be confused with various pneumococcal complications, chief of which are empyema and recrudescence of pneumonia. Pulmonary infarction may also be suspected. Empyema due to the pneumococcus rarely has such an explosive onset, it usually starts in an insidious manner, and signs of fluid in the pleural cavity frequently precede the fever. Recrudescence of lobar pneumonia occurs rarely, usually as the result of infection by a different organism than that originally found and with symptoms more like the onset of the primary pneumonia. Thomas¹³ demonstrated that remission of the original type of pneumococcal infection during convalescence

is unlikely because of acquired specific immunity. Pulmonary infarction resulting from thrombosis of a large blood vessel in the consolidated or resolving lobe is a not uncommon late complication of the disease. While its onset may be accompanied by violent symptoms, sudden stabbing pain, bloody sputum and dyspnea, it is more commonly an afebrile complication until secondary infection of the necrotic area occurs with subsequent abscess formation or gangrene. The presence of bloody sputum at the time of onset of the streptococcal infection in case 3 suggested the occurrence of pulmonary infarction, and this may have occurred.

The mode of infection by streptococci in convalescent patients is not completely understood. The organisms may be inhabitants in the mouth and nasopharynx of the patient or may be introduced by contact with individuals carrying streptococci, as was suggested by Cole and MacCallum³ and by Cumming, Spruit and Aten.⁴

CONCLUSIONS

Cases such as the three similar fatal cases of beta hemolytic streptococcal infection during convalescence from lobar pneumonia due to pneumococci that have been reported present a distinct clinical picture. A small proportion of the deaths recorded as due to lobar pneumonia can be attributed to streptococcal sepsis arising during convalescence from lobar pneumonia.

AMIDOPYRINE IN THE TREATMENT OF MEASLES

MAXWELL P. BOROVSKY, M.D.

AND

FREDERICK STEIGMANN, M.D.

CHICAGO

In recent years, medical literature has included several reports on the specificity of amidopyrine (pyramidon) in the treatment of measles.

Amidopyrine as a therapeutic agent in measles was first mentioned by Loewenthal¹ in 1924. In his report he stated that amidopyrine, when administered at or before the appearance of the rash, will cause (1) reduction of temperature to normal or nearly normal within twelve hours, (2) inhibition of eruption, at times completely, almost always partially, (3) immediate euphoria, (4) clearing up of conjunctivitis, coryza and cough within a day or two.

On these studies Loewenthal concluded that "the drug acts as promptly in measles as quinine does in malaria, or the salicylates in rheumatic fever. A drug which checks the onward march of the symptoms, and particularly the development of the rash, surely has the right to be called a specific drug."

Independent of Loewenthal's observations and discovery of amidopyrine as a "specific for measles," Dr. Hoyne² had used this drug in a small outbreak of measles in Chicago and later on as a routine treatment of the disease in various hospitals of this city. In a report of his observations (1929) he mentioned that amidopyrine is a most remarkable remedy in the treatment of measles and that he thought it acted as a "specific." He considered amidopyrine the most important therapeutic agent in the treatment of measles.

because (1) it reduced temperature without injury to the patient, (2) it allayed cough and appeared to lessen the irritation of all mucous membranes (3) it was of value in lessening complications and therefore tended to shorten the course of the disease and to lower the mortality rate

Following the reports of Loewenthal and Hoyne, several other reports dealing with amidopyrine as a therapeutic agent in measles appeared in the British medical literature. Thus Gladstone³ in 1930 reported a series of twenty-four cases treated with amidopyrine. He reported a temperature drop within the first twenty-four hours with no respiratory complications and further stated that nearly all patients were well on the fourth day. He also stated that when the drug was given in the Koplik spot stage a rash was scarcely evident. He believed that the drug was of particular value for younger individuals, but not so effective for older patients.

In support of Gladstone's observations, Urquhart and Winchester⁴ reported six cases treated with amidopyrine in which there was also a fall in temperature within twenty-four hours and disappearance of the cough and bronchitis. They thought the drug almost a "specific" but thought that it might cause a hemorrhagic rash.

Collier,⁵ in reporting a group of twenty-six cases of measles treated with amidopyrine, states that, of five patients who were thus treated during the stage of invasion on appearance of Koplik spots, only two developed a rash and all were well in two days. Sixteen patients treated at the onset of the rash showed an immediate reduction of temperature and they were well in from three to four days, while five cases treated in various late stages showed only little, if any, beneficial effect. On these observations he concluded that the marked features of this use of amidopyrine are (1) fall of temperature within the first day, (2) alleviation of cough, and (3) absence of complications. He believed that if the drug is administered in the stage of Koplik spots the disease is aborted. He stated, however, that the type of the case, mild or severe, determined the result.

In a later paper, Collier, in collaboration with Ronaldson⁶ reported 150 cases of measles treated with amidopyrine and concluded that amidopyrine is of most value in early cases, that it lessens the tendency to pneumonia and that it prevents complications. They stated that they could not substantiate the claim that the drug exercises a specific action or that it causes an abortion of the rash. They believe that the drug has no constant effect on the exanthem of measles. They therefore consider amidopyrine a valuable adjuvant in the treatment of measles and think that its action is chiefly antipyretic but that it appears to have some influence on other symptoms of the disease.

Attlee⁷ reported 129 cases, in 9 of which amidopyrine was given. In the cases in which amidopyrine was not administered there was a rise in temperature with the appearance of the rash and then an abrupt fall within twenty-four hours, only six cases showed some complications (bronchitis in four, bilateral otitis in two). In the nine cases in which amidopyrine was

given there was a slower appearance of the rash with a longer duration of the fever, while the complications were much more frequent. He concludes, therefore, that amidopyrine should not be given in measles.

There is apparently a conflict of opinion as to the value of amidopyrine in the treatment of measles. One group thinks that amidopyrine is a "specific," while another believes that it should not be used at all. A third group considers amidopyrine merely an adjuvant in the treatment of this disease, influencing it only as would any other antipyretic.

In order to observe the action of this drug first hand in the prophylaxis and treatment of measles, a series of 194 cases was studied in the contagious department of Cook County Hospital during the first six months of 1931. Alternate patients entering the institution

TABLE 1—Day of Return to Normal Temperature Level in Group of Patients Receiving and Those Not Receiving Amidopyrine

Stage of Eruption on Admission	Number of Patients with Day of Return to Normal Temperature Level										
	1st	2d	3d	4th	5th	6th	7th	8th	9th	10th	16th
First day 80 patients											
41 without amidopyrine treatment	3	10	13	8	4	2	0	0	1	0	0
39 with amidopyrine treatment	1	10	5	8	2	0	2	0	0	1	1
Second day 30 patients											
10 without amidopyrine	4	2	3	1	0	0	0	0	0	0	0
20 with amidopyrine	1	0	5	2	2	0	0	1	0	0	0
Third day 11 patients											
7 without amidopyrine	1	4	1	1	0	0	0	0	0	0	0
4 with amidopyrine	1	1	2	0	0	0	0	0	0	0	0
Fourth day 3 patients											
1 without amidopyrine	1	0	0	0	0	0	0	0	0	0	0
2 with amidopyrine	0	1	0	0	0	0	0	0	0	0	1
Sixth day 2 patients											
1 without amidopyrine	0	1	0	0	0	0	0	0	0	0	0
1 with amidopyrine	0	0	1	0	0	0	0	0	0	0	0

received amidopyrine, 1 grain (0.065 Gm.) for each year, up to 5 grains (0.3 Gm.) three times a day for ages above 5 years. The series includes ninety-five patients who received amidopyrine and ninety-nine to whom the drug was not administered.

On entrance the majority of patients bore the usual symptoms of measles: characteristic rash, coryza, conjunctivitis and bronchitis. One patient had broncho-pneumonia on admission. In all cases an attempt was made to determine the duration of the rash, but in sixty-nine this could not be learned. Eighty entered the hospital on the first day of the appearance of the rash: thirty within forty-eight hours, eleven within seventy-two hours, three within ninety-six hours, and two on the sixth day after the eruption. One patient entered without an eruption but developed the rash on the fourth day after admission (this patient received amidopyrine).

Of the eighty patients who entered on the first day of the eruption, thirty-nine received amidopyrine while forty-one did not. In the nonamidopyrine cases the temperature dropped to normal as follows: three on the first day, ten on the second, thirteen on the third, eight on the fourth, four on the fifth, two on the sixth, and one on the ninth day. The average duration of fever was 3.3 days.

³ Gladstone M. B. Brit. M. J. 1: 1198 (June 28) 1930. ² 1103 (Dec. 27) 1930.

⁴ Urquhart G. H. and Winchester A. H. Brit. M. J. 1: 1153 (June 21) 1930.

⁵ Collier J. I. Brit. M. J. 1: 1093 (June 14) 1930.

⁶ Ronaldson G. W. and Collier J. I. Brit. M. J. 2: 994 (Dec. 13) 1930.

⁷ Attlee W. H. W. Brit. M. J. 2: 996 (Dec. 13) 1930.

In the amidopyrine treated cases the temperature dropped to normal as follows: one on the first day, nineteen on the second, five on the third, eight on the fourth, two on the fifth, two on the seventh, one on the fifteenth, and one on the sixteenth day. The average duration of fever was 3.6 days.

Of the patients who entered with a rash of two days' duration, ten had not been given amidopyrine and twenty had received it. In the former, the average duration of temperature was 2.1 days; in the latter, 3 days.

Of eleven patients who entered the hospital on the third day of rash, seven did not receive amidopyrine and showed an average duration of fever of 2.3 days, while four who did receive amidopyrine had fever for an average of 2.25 days.

Of the three patients who entered on the fourth day of rash, the one who did not receive amidopyrine was afebrile the following day. Two received amidopyrine, one became afebrile on the second day, the other developed a complication and a fever of sixteen days' persistence.

Of the two patients who supposedly had a rash for six days, the one who did not receive amidopyrine became afebrile on the second day, the one receiving amidopyrine became afebrile on the third day.

With the duration of the fever as a criterion, we found that the temperature dropped the first day after admission in 22 patients: 11 to whom amidopyrine had been administered and 11 to whom it had not been given. On the second day the temperature dropped in 63 patients, of whom 37 had received amidopyrine while 26 had not. Forty-two cases became afebrile on the third day: 18 with amidopyrine dosage, 24 without it. On the fourth day the temperature dropped in 29 patients, of whom 15 had and 14 had not been given amidopyrine. The temperature dropped in 15 cases on the fifth day, of which 5 were treated with amidopyrine, while 10 were not. Six cases became afebrile on the sixth day: 2 with amidopyrine and 4 without it. Of 10 cases that had an afebrile course, 8 were in the group that did not receive amidopyrine and 2 among those which did receive the drug. Of the cases with prolonged fever, 2 were in the nonamidopyrine group

TABLE 2—Day on Which Temperature Returned to Normal in One Hundred and Eighty Three Cases

Days on which temperature dropped to normal	1st	2d	3d	4th	5th	6th	8th	9th	10th	16th
Number of cases treated with amidopyrine	11	37	18	15	5	2	1	1	1	1
Number of cases without amidopyrine	11	26	24	14	10	4	0	1	1	0

—nine and fifteen days, respectively—while 4 were in the amidopyrine group—eight, nine, fifteen and sixteen days, respectively (table 2).

Twenty-seven patients in this series developed complications. Of these, 11 received no amidopyrine, while 16 were given the drug. Among the 11 in the non-amidopyrine group, there were 4 with bronchopneumonia (one having entered the hospital with this complication), 5 cases of unilateral otitis media (1 of these being in a patient with bronchopneumonia), 1 bilateral otitis media, and 1 abscess of the thigh.

Among the amidopyrine group, bronchopneumonia developed in 2 cases, unilateral otitis media in 9, a bilateral otitis media in 1 case, diphtheria and cervical adenitis in 2 cases each.

Since, as already stated, all cases entered the hospital when the rash had already appeared, the effectiveness or noneffectiveness of amidopyrine in the prevention of the rash could not be observed. Only one case entered in the Koplik spot stage before the appearance of the rash. This case in the amidopyrine group developed a full blown eruption on the fourth day after admission. No marked difference in the persistence of the rash was noted in the two groups, nor was there any striking difference in the symptoms of conjunctivitis or coryza, among the patients of the two groups.

COMMENT

In 194 unselected cases of measles in which amidopyrine was given in alternate cases (dosage as stated),

TABLE 3—Patients with Complications

Type	Broncho-pneu-monia	Uni-lateral Otitis	Cervi-cal Adenitis	Diph-theria	Bilateral Otitis	Abscess of Thigh	Total
With amidopyrine treatment	2	9	2	2	1	0	16
Without amidopyrine treatment	4	5	0	0	1	1	11

* One patient had bronchopneumonia on entrance.

no striking difference was noted in the clinical course of the two groups. Nothing that would indicate therapeutic value was noted in the cases in which amidopyrine was given. The same clinical picture appeared in those in which this drug was not given and in those in which other antipyretics were given. There were no appreciable differences in the duration of fever or speed of convalescence among the two groups. Complications were about evenly distributed in the two groups.

In our investigation we have obtained results which make us believe that amidopyrine should be used as an adjuvant in the treatment of measles similar to any other antipyretic. This drug proved neither a 'specific' nor a harmful agent in the treatment of measles.

SUMMARY

1. Of 194 patients with measles admitted to the contagious division of the Cook County Hospital during the first six months of 1931, about one half received the amidopyrine treatment, while the remainder did not.

2. The morbidity, duration of fever, and complications were about equal in the two groups.

3. Amidopyrine did not prevent the appearance of the rash (one patient who entered the hospital and received amidopyrine developed a rash on the fourth day).

4. Complications occurred with equal frequency and severity in the two groups.

5. No marked drop of temperature was noted in the amidopyrine group as compared with the nonamidopyrine group, although a greater number of those in the amidopyrine group became afebrile on the second day.

6. Amidopyrine is not a specific for measles. It is a valuable antipyretic adjuvant in the treatment of the disease but should not be considered a specific.

CONCLUSIONS

1. Amidopyrine did not prevent the eruption of measles in the one case in this series seen in the pre-eruptive state.

2. It did not lessen complications.

3. It did not shorten the course of the disease.

Clinical Notes, Suggestions and New Instruments

A NONTRAUMATIC PHARYNGEAL AIRWAY

ARTHUR E. GUFDEL, M.D. BEVERLY HILLS, CALIF.

The pharyngeal airway has become an indispensable part of the anesthetist's equipment. Heretofore, various forms have been made of metal but metal airways are all more or less traumatizing, even when carefully used frequently producing cut or bruised lips, chipped or broken teeth, or lacerations of the pharyngeal mucosa.

The airway herewith depicted is made of rubber and is sufficiently soft and flexible not to traumatize yet amply rigid

Pharyngeal airway made of rubber with metal insert for mouthpiece.

to maintain an open oropharyngeal air passage under all conditions. Its flexibility permits it to conform to the varied oropharyngeal curves in different individuals.

The metal insert extends into the airway for about 2 cm. from the oral opening and prevents collapse of the rubber between the teeth.

520 North Bedford Drive.

TREATMENT OF A CASE OF ILLUMINATING GAS POISONING WITH METHYLENE BLUE SOLUTION

JOEL NASS, M.D. ALLENTOWN, PA.

F. H., a man, aged 24, was found by his mother, April 20, 1933, lying unconscious on the kitchen floor, in a room full of illuminating gas. He had been alone in the kitchen from 1:30 until 3:30 p.m. She dragged him to the back room and opened the door to admit fresh air. At that time, she says, he was unconscious and barely breathing.

When seen at 3:45 he was still unconscious, breathing at the rate of about 5 per minute, the respirations coming in short gulps. Time was not taken to determine the frequency of respiration, as immediate action was indicated. The neck and face were light pink, the lips were blue, and the pupils were dilated. The pulse was not perceptible at the wrists, and the heart action was poor, the rate probably about 90 per minute regular, but of poor muscular quality.

Artificial respiration was instituted immediately and was kept up during the administration of the methylene blue. Approximately 45 cc. of 1 per cent methylene blue solution was given slowly into the left antecubital vein. All the veins were dis-

tended, including those of the neck. It was evident that the circulation was impaired and sluggish, for it was necessary to aspirate firmly, to make sure that the needle was in the vein. About the time that the last 10 cc. was being injected, the patient's eyes opened and he uttered a few intelligible words. His respirations deepened, and with the completion of the injection the breathing was markedly improved and the pulse was obtainable at the wrist.

He was immediately removed to the Sacred Heart Hospital where he was given continuous inhalations of carbon dioxide and oxygen by means of a Gwathmey machine. The pulse at that time was weak, with a rate of 108. The blood pressure was 120 systolic, 95 diastolic, and the axillary temperature 95. Treatment consisted in elevation of the foot of the bed, hot water bags and blankets. Next was given an intravenous infusion of 10 per cent dextrose in physiologic solution of sodium chloride. Preceding the intravenous manipulation, several chills occurred, lasting about two minutes. Following the infusion, the patient was conscious but stuporous. Caffeine sodobenzoate, $7\frac{1}{2}$ grains (0.5 Gm.), was administered intramuscularly and continued every fourth hour. By this time the color was better, and the pulse full. The carbon dioxide-oxygen was discontinued, and normal respiratory movements ensued. By 7 p.m. he had reacted fully. The temperature was 99, pulse 100, respiration 20. He was extremely thirsty and suffered from nausea. At 11:30 p.m. he was fully aware of his surroundings and apparently out of danger.

After-care was symptomatic, and to date nothing in the way of complications has arisen. On being questioned, his first recollections were those in the hospital following the intravenous injection of dextrose and saline solution. He remembers nothing of the period of wakefulness following the injection of the methylene blue in the home.

1115 Hamilton Street.

SPONTANEOUS RUPTURE OF A CAVERNOUS ANGIOMA OF THE SPLEEN

CHARLES EVERETT HAINES, M.D. AND P. T. McILROY, M.D.
NEW ROCHELLE, N. Y.

Cavernous angioma of the spleen is rare. Ewing quotes Dowd as having collected only thirteen cases of angioma of the spleen through 1913.¹ Again, while rupture of the spleen is fairly common, spontaneous rupture of a cavernous angioma of the spleen is rare.

REPORT OF CASE

History—A woman, aged 43, white, married, had had irregular attacks of indigestion, and several attacks of arthritis possibly traceable to infections at the roots of the teeth.

About twenty-four hours before coming to the hospital, while standing in the preparation of dinner the patient was seized with extremely severe, sudden pain in the epigastrium. Her husband and her son and daughter were with her at the time of the seizure, they agreed with her that there had been no trauma.

The patient was immediately put to bed but a physician was not called at the time. Within an hour she became nauseated, she vomited and continued to vomit several times an hour for twenty-four hours. The pain was severe, continuous and burning during this period. It was mainly in the epigastrium, although there was moderate pain in the right lower quadrant.

Physical Examination—The patient appeared prematurely senile and poorly nourished and was acutely ill. Vomiting was frequent. She could be aroused but was semicomatose. She gasped for air as though she had lost a large quantity of blood.

The temperature was 101.4 F. by rectum, the pulse was 115 per minute, respirations were 25 per minute. The skin and tongue were dehydrated. The heart sounds were weak and rapid but regular. The blood pressure was 120 systolic, 75 diastolic.

The abdomen was very slightly distended and soft. There seemed to be fluid within the abdominal cavity. The entire abdomen was tender, exquisitely tender in the epigastrium and

¹ Ewing, James. Neoplastic Diseases. Philadelphia: W. B. Saunders Company, 1928.

moderately tender in both upper quadrants. There was also tenderness in the left costovertebral angle. The vagina and rectum were normal. The diagnosis was acute perforation of a gastric ulcer. Immediate operation was advised.

Operation—Before operation the patient was given 1000 cc of physiologic solution of sodium chloride and 1000 cc. of 5 per cent dextrose by hypodermoclysis. The abdomen was opened through an upper right rectus incision, the incision was later extended to the left lower costal margin.

When the peritoneum was opened, bright red blood welled into the wound. The spleen was palpated and found surrounded by fresh adhesions. The adhesions were broken up. The pedicle was tied and the spleen was removed. The free blood was left in the peritoneal cavity, which was closed without drainage. A transfusion of 500 cc. of blood was given before the patient was taken from the operating room.

Postoperative Course—After the patient was returned to bed she was given 1000 cc of physiologic solution of sodium chloride and 1,000 cc. of 5 per cent dextrose by hypodermoclysis. A similar hypodermoclysis was given six hours later and again twelve hours later. Twenty-two hours after operation she was given 200 cc. of dextrose intravenously. Three hours after this another transfusion of 500 cc. of whole blood was given. The following day another hypodermoclysis was given.

The heart became weaker and weaker in spite of the administration of caffeine sodiobenzoate. Vomiting could not be controlled by a duodenal tube, and pain and restlessness could not be controlled by large doses of morphine.

Death occurred forty-eight hours after operation.

Pathologic Report—The specimen consisted of a spleen measuring 10 cm in length, up to 5 cm in width and up to 4 cm in thickness. The capsule presented a wrinkled appearance. The spleen was firm in consistency and cut with considerable resistance. The pulp was grayish red. At one point near the upper pole was a collection of cystlike spaces containing blood. The largest of these communicated with the diaphragmatic surface. The spaces varied from the size of a pinhead to that of a pea.

Microscopic examination of the tissue taken from the area at which the hemorrhage occurred showed the presence of circumscribed spaces surrounded by fibrocellular connective tissue. The spaces were lined by flattened endothelium, they contained blood.

The pathologic diagnosis was cavernous angioma of the spleen.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.
H. A. CARTER, Secretary

ACCEPTANCE OF SUNLAMPS

During the past seven years the Council on Physical Therapy has devoted much time and effort to the question of ultraviolet radiation therapy, and in a preliminary statement¹ last July gave its findings and its specifications for acceptance of "sunlamps," by which term is understood a lamp that, at a specified distance, emits ultraviolet radiation not differing essentially from that of the clearest weather, midday, midsummer, midlatitude, sea level, natural sunlight, in total intensity and in spectral range of wavelengths extending from about 2900 to and including, 3,130 angstroms, and that does not emit an appreciable amount of ultraviolet radiation of wavelengths shorter than 2800 angstroms.

Sunlamps, so called, are not to be confused with therapeutic ultraviolet generators designed for service in hospitals, clinics and offices of physicians. Since sunlamps are for unsupervised home use they are often of low intensity, to avoid injury from overdosage.

After extensive investigation and inquiry in collaboration with physicists and other scientists acting as consultants and after due consideration of the status of ultraviolet radiation therapy, the Council on Physical Therapy has adopted and, until a more practicable and reliable procedure is proposed, will use the erythematous reaction as a basis for judging the effectiveness of a sunlamp, for the following reasons:

(a) The erythemal response is in common use as an indicator of skin tolerance and of the amount of ultraviolet radiation than can be applied at one time and so long as the present day types of ultraviolet generators are used, the erythemal test will be necessary to prevent injury from burns.

(b) It is practically the only physiologic reaction to ultraviolet rays that is established with a relatively high degree of accuracy, permitting a calculation of the approximate time of exposure from a simple physical measurement of the ultraviolet radiant flux emitted by the lamp.

(c) It is a simple and practicable means of preventing severe burns when using powerful sources of ultraviolet radiation.

(d) It is an efficient safeguard against the fraudulent sale of lamps that emit little or no radiation of wavelengths shorter than about 3,130 angstroms, generally accepted as having a specific therapeutic value in preventing rickets.

In an adopted article entitled "Ultraviolet Radiation Useful for Therapeutic Purposes—Specification of Minimum Intensity or Radiant Flux," by Dr. W. W. Coblenz, the Council has definitely specified the types of ultraviolet radiation generators that possess sufficient ultraviolet energy to be of therapeutic value. Furthermore, the Council has drafted two lists of requirements to govern advertising of ultraviolet generators to the public and to the profession.²

The Council's specifications of minimum intensity are based on a comfortable and convenient operating distance (namely, 24 inches, or 61 cm) from the front edge of the reflector at which distance the exposure can be made without burning the skin. The ultraviolet intensity of the lamp shall be such that the time of exposure to obtain a minimum perceptible erythema (if such a dose is desired) is 60 minutes, or a total of 120 minutes for a complete exposure front and back. In this connection it is relevant to note that the Council does not prescribe the dosage of ultraviolet radiation. Its function is to advise and protect the medical profession and the public against misleading and deceptive advertising in connection with the manufacture and sale of devices for use in physical therapy.

In view of the increasing number of so-called sunlamps, some emitting so little ultraviolet that from ten to twenty hours would be required to obtain an erythemal dose, the purchaser of a sunlamp has a right to expect, and the Council on Physical Therapy requires the ultraviolet output to be sufficiently strong relative to the total heat emanating from the lamp, that, if an erythemal dose is desired in fifteen minutes, the operating distance can be shortened without burning the bare skin by the heat ("heat burn") of the lamp in its reflector.

Physiologic experiments show that for practical purposes the wavelength of maximum erythemogenic action may be taken at the emission line of homogeneous radiation of mercury vapor, at 2,967 angstroms, present in many sources of ultraviolet radiation. The erythemogenic efficiency of this emission line is practically 100 per cent. No other wavelength or group of wavelengths, in any source, has such a high efficiency in generating an erythema.

For example, the erythemogenic efficiency (these values are subject to slight revision when better known) of the ultraviolet of wavelengths shorter than and including 3,130 angstroms, in sea level, midlatitude, noonday June sunlight, is about 0.22 (22 per cent), the Mazda type S-1 lamp 0.24, the Mazda type S-2 lamp, 0.215, the low temperature, type G, mercury vapor glow lamp, 0.185, the so-called cold quartz, low temperature, low vapor pressure, mercury arc, 0.55, the high temperature, high vapor pressure, quartz mercury arc, 0.344, the blue flame carbon arc lamp, 0.42, and the Mazda CX tungsten filament lamp, from 0.16 to 0.20, depending on the temperature of the filament.

The intensity and the erythemogenic action of the emission line of mercury at 2,967 angstroms is easily evaluated in absolute units, and the erythemal action, as well as the radio-

¹ Acceptance of Sunlamps. A Preliminary Statement. J. A. M. A. 99:31 (July 2) 1932.

² Regulations to Govern Advertising of Ultraviolet Generators to the Medical Profession Only and Regulations to Govern Advertising of Ultraviolet Generators to the Public Only.

metric output of heterogeneous ultraviolet radiation from various sources is easily correlated with this emission line as a standard.

The Council has therefore adopted 20 microwatts per square centimeter of homogeneous radiation of wavelength 2,967 as the erythral unit (E U) of dosage, that is, 1 E. U. = 20 microwatts per square centimeter of wavelength 2,967 angstroms. The amount of ultraviolet radiation of wavelengths shorter than and including 3,130 angstroms that a source must emit equivalent to 20 microwatts per square centimeter of homogeneous radiation of wavelength 2,967 angstroms, is obtained by dividing the 20 microwatts by the erythemogenic efficiency of the source in question. For example the erythemogenic equivalent of standard sunlight is $(20 \div 0.22 =) 91$ microwatts per square centimeter, and for the type G mercury vapor glow lamp it is $(20 \div 0.185 =) 108$ microwatts per square centimeter.

From the foregoing specifications it follows that in order to produce a minimum perceptible erythema on the average skin in 15 minutes for therapeutic lamps and in 60 minutes for so-called sun lamps the erythemogenic equivalent of the heterogeneous ultraviolet radiant flux of wavelengths shorter than and including 3,130 angstroms emitted by the various above mentioned sources must be as follows (Erythral Unit E U)

- 1 E. U. = 20 microwatts per sq. cm. of homogeneous radiation of wavelength 2,967 angstroms exposure 15 minutes
- = 5 microwatts per sq. cm. of homogeneous radiation of wavelength 2,967 angstroms exposure 60 minutes
- = 91 microwatts per sq. cm. of midday midsummer midlatitude sea level ultraviolet solar radiation exposure 15 minutes
- = 23 microwatts per sq. cm. of midday midsummer midlatitude sea level ultraviolet solar radiation exposure 60 minutes
- = 83 microwatts per sq. cm. of Mazda type S 1 lamp radiation exposure 15 minutes.
- = 21 microwatts per sq. cm. of Mazda type S 1 lamp radiation exposure 60 minutes.
- = 93 microwatts per sq. cm. of Mazda type S 2 lamp radiation exposure 15 minutes.
- = 23 microwatts per sq. cm. of Mazda type S 2 lamp radiation exposure 60 minutes.
- = 108 microwatts per sq. cm. of low temperature, type G mercury vapor glow lamp radiation exposure 15 minutes
- = 27 microwatts per sq. cm. of low temperature type G mercury vapor glow lamp radiation exposure 60 minutes
- = 58 microwatts per sq. cm. of high temperature high vapor pressure, quartz mercury arc radiation exposure 15 minutes.
- = 145 microwatts per sq. cm. of high temperature high vapor pressure quartz mercury arc radiation exposure 60 minutes
- = 36 microwatts per sq. cm. of cold quartz low temperature, low vapor pressure quartz mercury arc radiation exposure 15 minutes.
- = 9 microwatts per sq. cm. of 'cold quartz, low temperature, low vapor pressure quartz mercury arc radiation exposure 60 minutes
- = 48 microwatts per sq. cm. of blue flame carbon arc lamp radiation (in reflector no filter window) exposure 15 minutes.
- = 12 microwatts per sq. cm. of blue flame carbon arc lamp radiation (in reflector no filter window) exposure 60 minutes

The foregoing correlation of erythemogenic equivalents of various lamps is to be used in the following manner. Suppose, for example, that a type G mercury vapor glow lamp is submitted to the Council for acceptance and that the radiometric measurements at 24 inches (61 cm.) indicate an ultraviolet radiant flux of 9 microwatts per square centimeter. Since this is only $(9 \div 27 =)$ one third of the minimum requirement for this type of sunlamp, it will be necessary to prolong the exposure for $(3 \times 60 =)$ 180 minutes (3 hours) if it is desired to obtain an erythral dose with the lamp at 24 inches. Obviously such a lamp does not comply with the Council's specifications.

In the low temperature glow lamps which have a low infra-red output, it may not be found objectionable to shorten the operating distance in order to shorten the time of exposure. On the other hand in the case of the tungsten filament lamp, the large amount of heat from the filament and from the glass bulb may become intolerable when the lamp is operated close to the body.

From time to time, acceptances or rejections of sunlamps for home use will be published in the columns of the Council on Physical Therapy in THE JOURNAL. In accepting sunlamps, the attention of the profession is called to the following:

A The Council on Physical Therapy definitely withholds acceptance of the postulatory principle of dual-purpose lighting, because it is highly theoretical and the promulgators of this

idea have not presented acceptable clinical evidence to the Council substantiating its therapeutic or prophylactic value.

B The Council on Physical Therapy declines to accept sun lamps if the manufacturer fails to state in all advertising matter and descriptive literature the distance between the lamp and the recipient required to equal the intensity of midday mid summer, midlatitude, sea level, natural sunlight. Thus in the acceptances that follow, the reader will note that the manufacturer has stated the distance the recipient should be from the sunlamp to receive the alleged benefits.

C. The manufacturers of acceptable sunlamps for home use have agreed to discontinue objectionable claims such as that exposure to ultraviolet rays increases or improves the tone of the tissues or of the body as a whole, stimulates metabolism, acts as a tonic, increases mental activity, maintains health, or tends to prevent colds, because these claims have not been conclusively substantiated by experimental evidence.

D The Council declines to sanction claims recorded in descriptive literature and advertising matter in which implication is made that the production of an erythema is unnecessary as a test of intensity, that suberythral doses are sufficient for therapeutic benefit. The Council believes that, while such statements may be made in good faith, they merely open the way to fraud by irresponsible vendors of alleged sources of ultraviolet radiation. Until further evidence is presented to prove otherwise, the Council declares that the erythema test is the only means of determining whether appreciable ultraviolet is emitted by the source.

In order that there can be no misunderstanding on the part of any one relative to the stand of the Council on Physical Therapy on the acceptance of sunlamps, the dual-purpose lighting and the suberythral dosage, the aforementioned stipulations are given to the profession that it may better understand the problems confronting the Council regarding ultraviolet radiation therapy. The Council will give careful consideration to clinical evidence scientifically gathered by controlled experiments.

COLLINS OXYGEN TENT ACCEPTABLE

The Collins Oxygen Tent, manufactured by Warren E. Collins, Inc., Boston, was submitted to the Council for consideration. The Council finds that it is a serviceable tent and will provide oxygen therapy for treatment of those cases which are amenable to oxygen therapy, such as the treatment of pneumonia and certain cardiac cases.

The tent canopy is provided with large nonflammable windows on all sides and extends the full width of the hospital bed. The motor blower is comparatively noiseless in operation and apparently capable of displacing 50 cubic feet of air per minute. It is mounted on the side of the ice compartment or cabinet. In this position the motor is accessible, and in case of necessity a new motor can be installed in a few moments. The firm claims that a spare motor accompanies each machine ready for instant use.

The cabinet of the Collins Oxygen Tent is made of steel finished in ivory enamel with chromium trimmings. It is insulated with a two-inch thickness of cork and is lined with heavy copper. A construction of the ice compartment is such that the air travels twice the height of the cabinet, coming in contact with more than two cubic feet of cracked ice. The ice capacity is 125 pounds and under ordinary conditions will last about twenty-four hours. The ice cabinet is mounted on rubber tired casters and serves as a support for the tent. A rheostat controls the speed of the motor blower and governs the temperature and humidity within reasonable limits. The firm claims it is possible to reduce the temperature in the tent 20 degrees below room temperature and maintain the humidity within normal limits. Provision is made for the use of soda lime. Part of the regular equipment is a simple oxygen analyzer furnished without extra cost.

The unit was investigated in a clinic acceptable to the Council. The investigation substantiated the physical and therapeutic claims made by the manufacturer and met the tentative specifications of minimum standards for oxygen tents (unpublished) adopted by the Council. The Council on Physical Therapy declares the Collins Oxygen Tent acceptable for inclusion in the list of accepted devices.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORTS
RAYMOND HERTWIG Secretary

NOT ACCEPTABLE

MRS KLEIN'S HOME MADE REAL EGG NOODLES

The F L Klein Noodle Company, Chicago, submitted to the Committee on Foods an egg noodle prepared from durum patent flour, whole eggs or egg yolk and salt, called 'Mrs Klein's Home Made Real Egg Noodles'

Discussion of Label—The name 'Mrs Klein's Home Made Real Egg Noodles,' in conjunction with the facsimile of a woman preparing noodles in the home kitchen and a bowl of eggs labeled 'fresh eggs' resting on a table, implies that these noodles are "home made" and that fresh shell eggs only are used. The noodles are prepared in a factory. The statement 'fresh egg noodles' also connotes that fresh eggs only and not 'storage eggs,' 'dried eggs' or "frozen eggs" are used which is not in accord with fact. It is further stated that 'In making my noodles I used twenty good fresh eggs to five pounds of fine wheat flour, and I mixed them by hand. Today Mrs Klein's Real Egg Noodles are mixed in electric mixers but I still use the same formula as when I made them by hand' which is not in keeping with submitted manufacturing formula. A considerably smaller proportion of eggs is used. It is alleged that the noodles are "recommended by physicians. They contain all the necessary vitamins." The claim 'recommended by physicians' is vague and meaningless. Should it be true that any number of physicians recommend this brand of noodles, then the statement should specifically state what the physicians recommend the noodles for. The noodles do not contain all the necessary vitamins. The name and claims are incorrect and misleading.

The company was advised of the Committee's report but has not demonstrated that it has acted on the recommendations. This egg noodle product will therefore not be listed among the Committee's accepted foods.

NOT ACCEPTABLE

VITABAR

The Vitamin Company of America, Incorporated, Orlando, Fla., submitted to the Committee on Foods a dextrose sweetened milk chocolate coated confection of mixed fruits with wheat embryo and added vitamin extracts called "Vitabar" and containing vitamins A, B (complex), C, D and E in substantial amounts. Later it was learned from a company member and a distributor that the product had been withdrawn from the market. A leaflet containing a new type of claims not passed on at the time of acceptance, however, is now being distributed by Eros and Company of Cleveland. The advertising prominently states "Endorsed by the highest medical authorities the American Medical Association. Vitabar was accepted by the Committee on Foods of the American Medical Association and not 'Endorsed by the American Medical Association.' It is stated "Vitamins are Health. Vitabar is nature's complete assurance of HEALTH. Vitamins mean LIFE—and Vitabar means VITAMINS." Vitamins are necessary for health, they neither assure nor give health which depends on many other factors than vitamins and nutrition. Vitabar is not 'Nature's complete assurance of Health.' Vitamins are essential nutrients of the diet as are protein, carbohydrate, fat and so on. Vitamins do not "mean life" nor do they possess any mysterious life properties as implied. It is stated, 'Lack of vitamin C often causes rheumatism.' Lack of vitamin C is a cause of scurvy, a deficiency disease, but not of rheumatism.

The claims are incorrect and deceptive and conflict with the Committee's principles and policies for sound advertising in the interest of public welfare and health. At the time of acceptance the company assumed the responsibility of controlling the advertising and keeping it within the scope of the Committee's requirements. This obligation the company has

disregarded, resorting instead to a "patent medicine" type of advertising. The previous acceptance is being withdrawn and the product will therefore no longer be listed among the Committee's accepted foods.

NOT ACCEPTABLE

LARABEE'S HIGH TOP FAMILY PATENT FLOUR (BLEACHED)

The Larabee Flour Mills Company of the Commander Larabee Corporation submitted to the Committee on Foods a flour composed of a mixture of standard patent' and first clear flours milled from hard winter wheat called Larabee's High Top Family Patent Flour (Bleached).

Discussion of Name—The designation 'High Top Family Patent Flour' is appropriate only for flour constructed of selected flour mill streams for making a blend superior in baking quality to 'straight flour and especially to a mixture of standard patent' and first clear flours. Patent flours from the baking standpoint are considered higher grade flours than 'straight' flour or blends of 'standard patent' and 'first clear' flours and usually demand a higher price. The present designation is incompatible with the nature of the flour, misinformative and misleading.

The corporation when informed of this opinion has not demonstrated willingness to change the designation accompanying the trade name in accordance with the Committee's recommendation. The flour will therefore not be listed among the Committee's accepted foods.

REPORTS OF THE COMMITTEE

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

OPTIMISTIC MILK BREAD (WHITE)

Manufacturer—Davis Standard Bread Company, Mignonette Street Los Angeles

Description—A white milk bread made by the straight dough method (method described in THE JOURNAL March 12 1932, p 889) prepared from white flour fresh whole milk, sucrose, salt, yeast, malt extract shortening and a yeast food containing calcium sulphate ammonium chloride sodium chloride and potassium bromate.

Analysis (submitted by manufacturer) —

	per cent
Moisture (entire loaf)	35.5
Asb	2.0
Fat	3.5
Protein (N × 6.25)	13.5
Crude fiber	0.4
Carbohydrates other than crude fiber (by difference)	45.1

Calories—27 per gram 77 per ounce

Claims of Manufacturer—Made with fresh milk conforms to the United States Department of Agriculture definition and standard for milk bread.

MARECHAL NEIL SELF RISING FLOUR (BLEACHED)

Manufacturer—Collin County Mill & Elevator Company, McKinney, Texas

Description—A self rising flour containing blended "hard and soft bleached patent flours, salt, calcium acid phosphate and baking soda.

Manufacture—The ingredients are mixed in definite proportions in a batch mixer and automatically packed in cotton bags. The flour is bleached with a mixture of benzoyl peroxide and calcium phosphate (1 part to 50,000 parts of flour) and with nitrogen trichloride (one-ninth ounce per 196 pounds).

Claims of Manufacturer—A self rising flour for home baking of cakes and biscuits.

TYPHOID CARRIERS AND THEIR TREATMENT

Carriers of typhoid bacilli are a menace because they are often the cause of epidemics of typhoid. Since these carriers are most difficult to cure, their recognition and treatment constitute a serious public health problem. Various estimates are given of the proportion of convalescents who become chronic carriers. Gill¹ reported that 10 per cent of typhoid convalescents in the Southern states become chronic carriers. In general, it is estimated that from 2 to 5 per cent of all typhoid patients become permanent carriers. Recently C. H. Browning² has published a thorough report for the Medical Research Council in England. Carriers are classed as temporary (a short period during convalescence) and chronic (those not cured spontaneously after one year) and further as chronic biliary, intestinal and urinary carriers. Statistics indicate that there are four or five female chronic carriers to one male. The spread of infection is commonly due to contamination of food, particularly milk, though the infection may be water borne, fly borne or transmitted through soiled linen or direct contact. A carrier may transmit the infection only at intervals, which may be separated by years of noninfective periods. The identification of the carrier depends on the isolation of typhoid bacilli from feces, duodenal contents, urine or other discharge. This is often difficult and may require repeated examinations. Browning relied on direct plating in MacConkey's bile medium, though accessory methods are described, as the Widal reaction and the complement fixation, opsonic index, and skin sensitivity tests. Prophylactic vaccination minimizes the incidence of carriers by lessening the number of severe attacks of typhoid. Browning states that compulsory powers ought to be exercised by public health officials to obtain for examination blood, feces and urine of all convalescents and

suspected carriers. When recognized, carriers must be instructed as to the disposal of excreta as well as to the importance of personal cleanliness. They should be forbidden to handle food or drink intended for others, and their movements and whereabouts must be reported to the public health officers.

The treatment of a typhoid carrier may be non-surgical or surgical and has for its object the prevention of the excretion of living typhoid bacilli in the feces or urine. Chemotherapy in the form of acriflavine, phenol derivatives for intestinal antiseptics, salicylates and alkalis have proved ineffective. Alteration in the intestinal flora induced by acidophilus milk has no effect on the carrier state. Bacteriophage, vaccine treatment and roentgen irradiation over the gallbladder also have no effect. Browning concludes that there is no satisfactory vaccine or drug treatment of the condition, although biliary drainage by the duodenal tube deserves to be tested further. However, in cases in which the gallbladder is the site of infection, surgical measures have been highly satisfactory. The procedures in general use are cholecystectomy with or without prolonged drainage of the hepatic duct, cholecystostomy, cholecystogastrostomy and sometimes appendectomy. Cholecystectomy has been the most frequent operation and appears to have cured 75 per cent of the cases so far recorded as treated by this method. During the investigation three chronic intestinal carriers were operated on, and as the result of thorough observation afterward, it is concluded that all were cured. A small proportion of fecal carriers are of the intestinal type and consequently do not respond to gallbladder surgery.

The number of urinary carriers is small as compared with fecal excretors. The site of infection and the state of the genito-urinary system should be ascertained. Urinary antiseptics, especially methenamine, have been used successfully. However, the presence of gross lesions in the urinary tract may cause the failure of antiseptic treatment. In some reported cases the infection was unilateral, and in such cases operative treatment (nephrotomy, nephrectomy) has resulted in cure.

This subject deserves continued interest, since the persistence of chronic carriers of typhoid bacilli means the sporadic and epidemic occurrence of typhoid.

THE FATE OF TARTARIC ACID IN MAN

Modern biochemistry has reversed the older conception as to the behavior of many organic acids in the body. Unlike the mineral acids, such as hydrochloric or sulphuric acid, not all the organic acids function as acids in intermediary metabolism. Some of them are "potential alkalis" in their mode of action, they may protect the body from loss of base. In earlier days the behavior of benzoic acid in the organism served as a sort of "model" for the action of the organic acids as a group. Benzoic acid, C_6H_5COOH , though entirely "organic" in its make-up, is not burned up in the body.

¹ Gill D. G. Epidemiology of Rural Typhoid. J. A. M. A. 89: 1198 (Oct. 8) 1927.

² Browning C. H. with Coulthard H. L., Cruickshank R., Guthrie K. J. and Smith R. P. Chronic Enteric Carriers and Their Treatment. Medical Research Council Special Report Series No. 179. London: His Majesty's Stationery Office, 1933.

It tends to conjugate with glycine and is excreted as hippuric acid. When benzoic acid is consumed in undue amounts, some of it may even be excreted as such by the kidneys. Oxalic acid, HOOC COOH , is another organic acid that seems to resist the oxidative capacities of the organism. Oxalates are well known constituents of the urine.

Several other organic acids are widely prevalent, often in considerable amounts, in our common foods. Thus citric, malic and tartaric acids occur in citrus fruits, apples and grapes, respectively. Citric acid is readily oxidized in the body. The drinking of large amounts of orange juice, which naturally contains it, actually results in the production of alkaline urines, as Blatherwick demonstrated long ago. In one of his publications he remarked that it is impossible under ordinary conditions to overreach the organism's ability to oxidize citric acid. This applied to an amount contained in a daily intake of orange juice in which an equivalent of 48 Gm was present.

The behavior of tartaric acids has been the subject of much debate. Underhill and Wells demonstrated years ago that large doses of tartrates may cause damage to the kidney tubules and serious disturbance in renal function. Nevertheless there was a widespread impression that tartrates can be oxidized to some extent in the body, though less readily than either citric, malic or succinic acids. Subsequently, however, Underhill, Leonard, Gross and Jaleski,¹ working in the Yale University School of Medicine, recorded results in animals which are at variance with earlier reports. In both rabbits and dogs, when nontoxic doses of tartrate were administered either orally or intramuscularly, they were able to recover from 74 to 99 per cent in the urine. When the dose of tartrate administered is sufficient to cause severe renal damage, the tartrate excretion is greatly diminished. In the rat, the average urinary output is 68 per cent and 79 per cent, respectively, for oral administration and subcutaneous injection. The guinea-pig, it was found, is unique in that it excretes in the urine up to 27 per cent of tartrates administered by mouth, and practically 100 per cent of tartrates given subcutaneously.

The situation with respect to man has remained somewhat inconclusive.² Studies by Finkle³ at the Mount Sinai Hospital in New York, however, support the conclusion that tartaric acid cannot be oxidized or otherwise utilized by human beings. When injected intramuscularly, tartaric acid reappears almost quantitatively in the urine within ten hours, the major portion being excreted within the first four hours. When taken by mouth, only about 20 per cent of ingested tartrate is eliminated in the urine. At no time in the course of

investigations have any traces of tartrate taken by mouth been demonstrated in the feces. It has long been known that tartaric acid is destroyed by fungi and by certain bacteria. According to Finkle it is therefore probable that the portion of tartaric acid given by mouth which fails to appear in the urine (80 per cent) is destroyed in the intestinal tract by bacterial action. Twenty per cent or less is absorbed before it is subjected to the destructive action of the intestinal bacteria and is excreted in the urine. The experiments of Pickens and Hetler⁴ are in accord with these results. They gave large quantities of grape juice to their subjects and found that the urine was acid and not alkaline as might be expected from feeding of malic or citric acid. The excretion in the urine of a part of the tartaric acid present in the grape juice may account for their results. Tartrates also form a part of some of the commonly used baking powders as well as being present in the laxative rochelle salt and seidlitz powder. In Finkle's studies on man, comparatively small doses were administered. Under such conditions, renal damage did not occur. He points out that it is therefore possible to recover practically all of the injected tartrate in the urine and to demonstrate that none of this fruit acid is utilized by human beings.

CARBOHYDRATES IN THE URINE

That small amounts of carbohydrate substances may be found in the urine of healthy persons has been frequently established. Part of the carbohydrate has been alleged to be a fermentable compound, while another portion is reported to be nonfermentable by yeast. The knowledge of these facts inevitably has a bearing on the consideration of diabetes, in fact, the problems of this disorder must have some intimate relation to the "normal" sugar excretion, if the latter conception is a justifiable one. The ability to demonstrate a carbohydrate substance in the urine of health depends on the delicacy of the test reactions employed.

In 1918, S. R. Benedict and his co-workers⁵ reached the conclusion, on the basis of careful investigations, that sugar elimination takes place, in small amounts of course, continuously through the urine. At that time they alleged that progress in the study of carbohydrate metabolism will probably be more rapid if the term "glycosuria" can be abolished. This word, they insist, was not created by the mind of man but by the inefficiency of the copper tests. Glycosuria implies a sudden point at which sugar appears in the urine. Since there is no such point, the term glycosuria is without special significance and is misleading. A term is needed, Benedict argues, to include both the constant presence of sugar in normal urine and an excess of

sugar elimination above the normal. Such a term would serve as a reminder to the student that the normal urine contains sugar that this sugar is subject to change through various influences, and that it is worthy of some attention. Possibly "glycuresis" would be a satisfactory term, as indicating increase of sugar, not a new appearance of sugar in the urine.

West and Steiner² of the Washington University School of Medicine in St. Louis have presented evidence that human urine, both normal and during starvation, contains fermentable sugar in the strict sense of the term and that this sugar is dextrose. In further studies in the same laboratories West, Lange and Peterson³ reached the conclusion that the excretion of fermentable sugar in normal urine seems to be related to the condition of activity of the pancreas and of the general carbohydrate metabolism. Conditions that lower the carbohydrate tolerance increase the fermentable sugar excreted and vice versa. This suggests that the small quantity of fermentable sugar of normal urine is dextrose and that Benedict's idea of a continual passage of blood sugar into the urine is correct. It should be emphasized, to avert all misconceptions, that the quantity of sugar passing is so small that it is not detectable by the ordinary qualitative tests and that it is of no clinical importance.

Several investigators seem to agree that the physiologic factors affecting the excretion of fermentable sugar in normal urine are quite unrelated to those controlling the excretion of the nonfermentable fraction, to which some reference has already been made. According to West, Lange and Peterson a diet entirely free from substances that will contribute to the nonfermentable fraction cannot be realized. Accordingly, a preliminary study was made to discover the foods which, taken in reasonable quantities, have no marked effect on the excretion of nonfermentable substances. It was found, in brief, that white bread, milk, potatoes, sucrose, starch, fats, peas, string beans, tomatoes, citrus fruits, canned pineapple and pears, strawberries, bananas, lettuce, cabbage, celery, eggs, cheese, farina, meats cooked without cereal, and some other articles of food can be taken rather interchangeably in mixed diets with a practically constant elimination of nonfermentable reducing substances. Ingestion of pure carbohydrates does not augment the nonfermentable urinary carbohydrate fraction. These results are in accord with the ideas of Folin and Berglund and others that much of the reducing material of normal urine represents unassimilable foreign and altered carbohydrate substances from the diet. Indeed, the St. Louis biochemists regard it as likely that practically all foods contribute something to this nonfermentable fraction,

which is apparently made up of a heterogeneous group of substances essentially non-nitrogenous, and probably chiefly carbohydrate in nature.

Current Comment

BOTULISM "CARRIERS"

Migrating birds, without signs of botulinus infection, may harbor viable spores of *Clostridium botulinum* in their livers, according to recent reports by Gunderson¹ of the University of Minnesota. These birds may serve as mechanical disseminators of this micro-organism to new soil areas. They constitute, therefore, a potential danger in carelessly prepared human food. While the data submitted are drawn mainly from migrating ducks, a carrier condition was occasionally demonstrated in apparently normal grouse. The condition could be produced experimentally in pigeons. In order to produce this condition, a botulinus culture was detoxified by heat (80° C for thirty minutes) and 1 cc of the nontoxic spore suspension was fed to pigeons. Forty-eight hours later viable micro-organisms were recovered from an occasional apparently normal liver. Whether or not the presence of minute traces of toxin in the ingested food would increase this percentage has not yet been determined.

POLYVALENT BACTERIOPHAGE

"Bacteriophage" as found in nature usually exhibits lytic action against only one narrow bacterial type. If apparently polyvalent bacteriophages are found, this polyvalence is usually due to the presence of several independent monovalent units, which can be separated by appropriate fractionation methods. Occasionally, however, an apparently true polyvalent bacteriophage is found that resists all attempts at such fractionation. Working with a trivalent bacteriophage of this character that satisfies all criteria of unity, Bronfenbrenner¹ of Washington University School of Medicine found that the bacteriophage would propagate equally well if grown in symbiosis with any one of the three susceptible bacterial types or species. Nevertheless this bacteriophage could be fractionally inactivated. If carefully heated in the presence of glycerin or saccharose, all but one of its specific monovalences were denatured or destroyed. Thus fractionally denatured, the bacteriophage is truly monovalent. It will grow and cause lysis only in symbiosis with one narrow bacterial type. The heterophile valencies thus denatured or destroyed, however, are quantitatively restored or regenerated on serial symbiosis with this one type. Bronfenbrenner believes he is dealing with a genus-specific rather than a narrow type-specific phagic colloid, conceivably directed against the heterophile fractional chemical component common to the three susceptible bacterial types. He quotes his data as evidence against the assumed parasitic nature of bacteriophage. If the bacteriophage were a parasite

capable of invading several bacterial types it is difficult for him to believe that heat could destroy its power of invading all but one type, while leaving the invasive power of this type largely unimpaired. Furthermore, to his mind, the subsequent recovery of the original polyvalent lytic power cannot be explained on the basis of "adaptivity" of the parasite to a new host. The regeneration of additional valences takes place in the absence of the bacterial types for which the regenerated bacteriophage becomes lytic. Since Bronfenbrenner was working with a bacteriophage for gastro-intestinal bacteria with anticolon specificity as the dominant or most resistant monovalence, his results are of more than mere academic interest.

Medical Economics

A NEW EXPERIMENT IN INDUSTRIAL MEDICINE

M S BLOOM, M D
BINGHAMTON N Y

A unique experiment in industrial medicine, which permits absolute freedom of choice, is under way in Binghamton, N Y. The experiment is sponsored by Spaulding Bakeries, Inc., wholesale bakers of bread and cake products. A study of the plan reveals certain facts which are of significance to the medical profession.

Although experience on this plan is limited to the one year of its operation, the sponsors are confident that no obstacles to its further continuation present themselves. I am medical adviser of the Spaulding Employees' Mutual Benefit Association as the Binghamton organization is called, and have worked intimately with the employers and employees in formulating the plan and supervising its operation.

This mutual benefit association is a voluntary organization of employees and is democratic in form. Executive control is vested in a board of governors, composed of officers elected by members of the association and by a board of trustees appointed by the president of the company. Revenue is derived by a system of dues, paid into the treasury by members and in proportion to the wage they receive by virtue of their employment. The company contributes to the fund on a dollar-for-dollar basis. That is, for each dollar collected in dues from the membership, the employer contributes one dollar to the association treasury.

A notable and highly significant fact is that the benefit association was originally organized in 1930 with medical service provided on the contract basis—a basis quite generally found at the present time in industrial medicine. Reasons for the change from a contract basis to freedom of choice, and the results of the change from the standpoint of the association members and the practicing physicians of the community, present many interesting developments.

Some business executives consider the health of their employees to be an economic problem, the adequate solution of which will show up advantageously in their reports. A few employers go further than that. Entirely apart from the economic aspects involved they take a personal interest in the health of the men and women whom they employ. Frequently employees are not considerate of their own physical well being, and this becomes a personal problem of the management and deserves thoughtful consideration. A combination of the economic aspects and of the purely personal significance of the problem within the organization led to the formation of the benefit association.

Under the plan as first organized in 1930 a group of physicians were selected under contract, to provide the necessary medical service. From time to time, members of the association reported that they preferred to go to their own family physician for treatment. Further, officers of the association came in contact with cases in which members continued with their family physicians, in spite of the fact that they were paying dues to the association. As time went on, the employers began to sense that local physicians not connected with the association opposed this type of organization, and the employers felt that this opposition was justified.

The subsequent change in the method of providing medical service was based on definite principles, arrived at by concrete experience. The president of the company felt that employees should be their own judges as to whom they should consult when they were sick. They sensed the tremendous advantage of the personal relationship that exists between physician and patient. The basis of this relationship was confidence. And secondly, medical service was not a commodity which could be bought and sold on a volume basis. The inherent character of the medical profession was independence and justly so because its problems are independent and personal.

With these basic views on the question, the only alternative to suspension of the activities of the association was its reorganization along entirely different lines. Benefits and services under the original plan were in general appreciated by the member-employees, and they did not want the association to be abandoned.

The president of the company called a joint meeting of the officers of the association, the presidents of the Broome County Medical Association, the Binghamton Academy of Medicine and the Binghamton Dental Society and myself. The whole problem was frankly and openly discussed and on the basis of this discussion E J Hotchkiss, president of R Z Spaulding Company, Inc., decided to try a pioneer experiment in industrial medicine.

The association was reorganized with freedom of choice the basic feature, this new plan to continue for one year. There was considerable doubt as to whether the association under its plan of reorganization could successfully operate over a period of time. But a safe financial reserve had been built up under the previous plan, and the worst that could happen would be the depletion of this reserve.

When the experimental period concluded in April, 1933, not only had the original reserve remained untouched but a substantial increase in the reserve had resulted under the new plan, embodying the principles of freedom of choice. At this time the executives of the company and the officers of the association see no reason why the activities of the association should not be continued indefinitely, and possibly extended if it seems advisable, to eight other bakeries operated by Spaulding Bakeries in New York State and Pennsylvania.

MEDICAL SERVICE UNDER THE SPAULDING PLAN

The functions of the benefit association are governed by a constitution and by-laws, adopted by the members. The facilities of community medical service agencies are used. Any member of the association may consult any physician whom he wishes. If an employee is sick, he simply obtains from the secretary of the association a form, which he presents to his physician. If the employee is unable to call at the office for the form, he reports this later to the secretary. Both house calls and office calls are permitted.

The members receive medical and surgical attention, including major and minor operations, eye, ear, nose and throat service, roentgen examination, dental service, limited to roentgen examination and extraction, laboratory, and ward service in the hospital, not exceeding thirty days in any one year, and at \$3 per day. When it is necessary to hospitalize a member,

benefits are not paid. They are paid, however, when the patient is released from the hospital except in case of surgical operation. The term "hospital" does not include a tuberculosis sanatorium or institutions for chronic diseases.

The association pays the prevailing medical and dental fees in the community. A special committee consisting of the president of the Broome County Medical Association, the president of the Binghamton Academy of Medicine and the president of the Binghamton Dental Society, and myself, was set up to pass on bills if there seemed to be any question of exorbitance or padding. To date this committee has not been called to confer on this problem.

Benefits are paid when a member is absent from work because of sickness. Members are entitled to ten weeks' sick relief during any one year. The scale of benefits is established in proportion to the amount of dues the particular member pays.

Restrictions are placed on the amount of money that may be expended for medical or dental services on any one member during the course of a year. The maximum is set at \$350 per member. House and office calls are limited to \$50 per member annually, and dental service to \$25 per member.

FINANCIAL ASPECTS OF THE PLAN

The membership of the association is divided into classes according to the wage received. There are four classes of employees. The dues paid by the classes are as follows: class 1, 20 cents a week; class 2, 25 cents; class 3, 35 cents; class 4, 45 cents.

For each dollar collected in membership dues the company contributes one dollar to the association treasury. In case of sickness class 1 members receive \$7.50 a week; class 2, \$10; class 3, \$15; class 4, \$20.

During the course of the first year's operation, association members consulted sixty-five different physicians and twenty-five different dentists.

CONCLUSIONS

While this experiment has been limited to a relatively small group of people and has extended over a short period its continued operation may bring forth some facts and methods of procedure that may be applicable to larger groups.

The history of the experiment up to this time indicates that small weekly payments by the employees supplemented by an equal contribution by the employer, makes possible the provision of a very satisfactory type of medical service with an acceptable and equitable distribution of costs and the application of the principle of freedom of choice.

The success of this plan, in a great measure, has been due to the splendid cooperation of the doctors and dentists in the community.

110 Oak Street.

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday from 9:15 to 9:20 a. m., Chicago daylight saving time, which is one hour faster than central standard time, over Station WBBM (770 kilocycles, or 389.4 meters).

The subjects for the week are as follows:

June 13 Hay Fever and Asthma.
June 15 Summer Cottage Safety

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9:45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

June 17 A Human Repair Shop.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Memorial Library—In memory of the late Howard W. Estill, D.Sc., assistant professor of bacteriology at the University of California Medical School, Mrs. Estill has given his chemical collection to the library of the medical school and the San Francisco branch of the state medical library. The gift of 150 volumes includes monographs and reference volumes relating to organic physical and colloid chemistry as applied to biology and medicine.

Personal—Dr. Addison W. Preston, Visalia, resigned as health officer of Tulare County, June 1, after twenty-five years' service, he was succeeded by Dr. Elmo R. Zumwalt, Tulare. —Dr. John H. Graves, president of the state board of health, was recently appointed medical director of the state industrial accident commission and state compensation insurance fund. —Dr. Ray C. Atkinson has been appointed health officer of Colfax, succeeding Dr. David M. Kindopp.

COLORADO

Society News—Speakers before the Boulder County Medical Society in Boulder, May 11, were Drs. John M. Foster Jr., Denver, on 'Carcinoma of the Lower Lip'; Duval Prey, Denver, 'Gunshot Wounds of the Abdomen,' and Wilfred S. Dennis, Denver, 'Duodenal Lesions Other Than Ulcer'. —A recent meeting of the Mesa County Medical Society was addressed in Grand Junction by Drs. James S. Orr, Fruita, and Frank J. McDonough on 'Morals and Venereal Diseases' and 'Injuries to the Head' respectively. —The El Paso County Medical Society was addressed April 12, by Dr. Louis S. Faust, Denver, among others on 'Diagnosis of Colitis'. —Drs. James E. Jeffery and Earnest O. McCleary, both of Ordway, will discuss fractures of the upper and lower extremities respectively, before the Crowley County Medical Society in Ordway, June 14. Among others, Dr. Harold T. Low, Pueblo, presented a motion picture before the society, May 10, on 'Transurethral Section of the Prostate'. —At a meeting of the Medical Society of the City and County of Denver April 30, a conference on medical economics was conducted by Abraham D. Kaplan, Ph.D., and Dr. Douglas W. Macomber.

CONNECTICUT

Dr. Blake Appointed to National Research Council—Dr. Francis G. Blake, Sterling professor of medicine, Yale University School of Medicine, was recently appointed chairman of the division of medical sciences of the National Research Council. Dr. Blake, who has been a member of the board of scientific directors of the Rockefeller Institute since 1924, has been a member of the division since 1925.

The One Hundred and Sixty-Ninth Annual Meeting—The Litchfield County Medical Society held its one hundred and sixty-ninth annual meeting at the Litchfield County Hospital April 25. Dr. Charles H. Carlin, Torrington, was elected president, Dr. Harry B. Hanchett, Torrington, vice president, and Dr. Wilmarth Bradford Walker, Cornwall, secretary. Speakers at the session included Drs. Arthur H. Jackson, Washington, on the nervous system, and Creighton Barker, New Haven, middle ear conditions.

DISTRICT OF COLUMBIA

Bill Introduced for Prevention of Blindness—S. 1787, introduced by Senator Copeland, New York, proposes to provide for the prevention of blindness in infants born in the District of Columbia.

Appointments at George Washington University—Announcement is made of the following new full time appointments at George Washington University School of Medicine, Washington:

Dr. Edward Bright Vedder, professor of experimental medicine and executive officer, department of pathology and experimental medicine.
William Henry Waller, Ph.D., instructor in anatomy.
Jesse Harmon, Ph.D., instructor in biochemistry.
Hubert Scott Loring, Ph.D., instructor in biochemistry.
Dr. James Leslie Snyder, instructor in pathology.
Dr. John Ralston Pate, teaching fellow in anatomy.

FLORIDA

Course in Medicine—The general extension division of the University of Florida is conducting a graduate course in medicine at the university, June 19-24, under the sponsorship of the Florida Medical Association. The registration fee is \$5. Instruction will be given by the following physicians:

Fred H. Albee, New York.
William Wayne Babcock, professor of surgery, Temple University School of Medicine, Philadelphia.
Cornelius G. Coakley, professor of otolaryngology, Columbia University College of Physicians and Surgeons, New York.
John A. Kolmer, professor of medicine at Temple.
Charles Jefferson Miller, New Orleans, professor of gynecology, Tulane University of Louisiana School of Medicine, New Orleans.
William A. Mulhern, professor of clinical pediatrics, University of Georgia Medical Department, Augusta.
James R. McCord, professor of obstetrics and gynecology, Emory University School of Medicine, Atlanta, Ga.

Members of the faculty of the University of Florida who will be among the instructors include Bernard V. Christensen, Ph.D., professor of pharmacognosy and pharmacology, Perry A. Foote, Ph.D., and William J. Husa, Ph.D., professors of pharmacy, and Townes R. Leigh, Ph.D., dean of the college of pharmacy. Local physicians who will assist in the teaching will be Drs. Lucien Y. Dyrenforth, Joseph Lee Kirby-Smith, Clayton E. Royce and Shaler A. Richardson, all of Jacksonville, and Dr. Joshua C. Dickinson, Tampa.

ILLINOIS

Immunization Campaign in Jackson County—A program of immunization against smallpox, diphtheria and typhoid is being carried on by the Jackson County Health Council, according to the *Illinois Health Messenger*. The county has been divided into thirteen districts in each of which popular meetings will be held, with an address by a member of the county medical society and motion picture films. Local civic agencies are cooperating. The Jackson County Health Council is composed of representatives of agencies interested in public health. The county medical society plans to hold a clinic for physically handicapped children during June.

Personal—Dr. George W. Morrow is now in charge of the Kankakee State Hospital, succeeding Dr. Roy O. Hawthorne, who, it is expected, will return to Monticello to resume private practice. Dr. Hawthorne was superintendent of the institution for two years.—Dr. Oscar J. Hagebush has resigned as manager of the Anna State Hospital, after four years' service. Dr. Daniel D. Coffey has resigned in a similar capacity at the Chicago State Hospital at Dunning, after twelve years' service.—Dr. Norman C. Bullock has been appointed health officer of Rockford, succeeding Dr. Nordahl O. Gunderson, who has held the position for ten years.—Dr. Frederick Grunck has been appointed consultant surgeon to Oak Forest Infirmary.

Chicago

Symposium on Silicosis—Dr. Henry K. Pancoast, professor of roentgenology, University of Pennsylvania School of Medicine, Philadelphia, and Dr. Anthony J. Lanza, assistant medical director, Metropolitan Life Insurance Company, New York, will participate in a meeting on silicosis, June 12, sponsored by the industrial committee of the Chicago Tuberculosis Institute at the Chicago Woman's Club. Dr. Pancoast will speak on "Roentgenologic Diagnosis and Differential Diagnosis in Connection with Silicosis," and Dr. Lanza, "Silicosis in the United States." Dinner will precede the meeting.

Capps Prize for 1933—The Joseph A. Capps Prize of \$500 is offered by the Institute of Medicine of Chicago for the most meritorious investigation in medicine or in the specialties of medicine. The investigation may be also in the fundamental sciences, provided the work has a definite bearing on some medical problem. Competition is open to graduates of Chicago medical schools who have received the degree of doctor of medicine during the year 1931 or thereafter. Manuscripts must be submitted to the secretary of the institute, 122 South Michigan Avenue, Chicago, not later than December 31.

Dr. Bensley Retires as Chairman—Charles Judson Herrick, Ph.D., professor of neurology in the department of anatomy at the University of Chicago since 1907, has been appointed chairman of the department. Before coming to the university in 1907, Dr. Herrick was professor of zoology at Denison University. He is the author of books on biology and neurologic subjects, and has been managing editor of the *Journal of Comparative Neurology* since 1894. Robert R. Bensley, D.Sc., the retiring chairman, will serve until July 1. Although professor emeritus, having reached the retiring age, he will continue to offer graduate work in the department during the next year. Dr. Bensley came to the University of Chicago in 1901 as assistant professor of anatomy. He has been professor since 1907 and chairman since 1913.

IOWA

State Medical Election—At the recent annual meeting of the Iowa State Medical Society, Dr. Charles B. Taylor, Ottumwa, was inducted into office as president. Dr. Gordon F. Harkness, Davenport, was named president-elect, and Drs. William E. Ash, Council Bluffs, and Frank H. Conner, Nevada, vice presidents. Dr. Robert L. Parker, Des Moines, was reelected secretary. The next annual session of the society will be held in Des Moines during the second week of May, 1934.

Conference on Child Development—The seventh annual Iowa Conference on Child Development and Parent Education will be held in Iowa City, June 20-22, under the auspices of the Iowa State Council for Child Study and Parent Education, in cooperation with the Iowa Child Welfare Research Station and Extension Division of the University of Iowa, Iowa State College of Agriculture and Mechanical Arts and the Iowa State Teachers' College. The program will be devoted to lectures, symposiums and round table discussions. An institute for child study leaders will be conducted, June 19-24.

KANSAS

New Officers for Health Association—At the conclusion of the annual school for health officers and public health nurses in Topeka, April 19, Dr. C. Herbert H. Munger, Emporia, health officer of Lyon County, was elected president of the Kansas Public Health Officers' Association. Other officers include Drs. Russell E. Hobbs, Wichita, health officer of Sedgwick County, vice president, and J. Carroll Montgomery, Topeka, secretary.

Personal—Dr. Isadore J. Berkowitz, Denton, was recently appointed health officer of Doniphan County, replacing Dr. John G. Swails, Wathena.—Dr. Edwin C. Morgan, Clay Center, was recently appointed a member of the Kansas Board of Registration and Examination to succeed Dr. Edgar C. Duncan, Fredonia.—Dr. Herbert A. Browne, Galena, has been appointed a member of the Kansas State Board of Health, filling the unexpired term of Dr. Harry H. Brookhart, Columbus, and Dr. Harry L. Aldrich, Caney, succeeding Dr. Charles M. Jenney, Salina.

LOUISIANA

State Medical Election—Dr. Carl A. Weiss, Baton Rouge, is the president of the Louisiana State Medical Society for the ensuing year. At a meeting of the house of delegates of the society, April 25, Dr. Stanford Chaille Jamison, New Orleans, was named president-elect and Drs. Joseph H. Slaughter, Bogalusa, Marcy J. Lyons, New Orleans, and George W. Wright, Monroe, vice presidents. Dr. Paul T. Talbot, New Orleans, was reelected secretary. The next annual meeting of the state medical society will be held in Shreveport, April 10-12, 1934. The meeting for 1933 which was to have been held at Lake Charles, April 25-27, was dispensed with.

MAINE

State Medical Meeting at Poland Spring, June 26-28—The eighty-first annual session of the Maine Medical Association will be held at Poland Spring, June 26-28, with headquarters at the Poland Spring House and under the presidency of Dr. Elmer D. Merrill, Dover-Foxcroft. Clarence C. Little, Sc.D., managing director, American Society for the Control of Cancer, Bar Harbor, will discuss "Research in Cancer." The program includes the following physicians:

Adam P. Leighton, Jr., Portland, Uterine Malignancy and Radium Therapy.
Charles H. Gordon, Portland, Infections of the Salivary Glands.
Magnus F. Ridler, Bangor, The Menopause.
Harold J. Everett, Portland, Prenatal Care Including Abnormalities and Complications of the Pregnant State.
Forrest C. Tyson, Augusta, Clinical Psychiatry for the General Practitioner.
John R. Hamel, Portland, Cardiorenal Disease and Hypertension.
Charles B. Sylvester, Portland, Allergic Cumulation and Explosion as Seen in Asthma.
Edward H. Risley, Waterville, Treatment of Acute Brain Injuries.
Charles B. Popplestone, Rockland, Differential Diagnosis of Spinal Cord Lesions.
Warren E. Kershner, Bath, Cycloplegia in Refraction.
Stephen E. Voshburgh, Pownall, Changing Views as to Cause and Transmission of Subnormality.
Elton R. Blaisdell, Portland, Treatment of Diabetes Mellitus with Special Reference to Its Complications.
William R. McAdams, Portland, and Erastus E. Holt, Portland, Ophthalmic Tuberculosis.
Ernest W. Files, Portland, Diagnosis and Treatment of Extra Uterine Pregnancy.

Dr. Howard F. Hill, Waterville, will conduct a special conference, Tuesday on "The Year's Progress in Ophthalmology" and Dr. Frederick T. Hill, Waterville, one on "The Year's Progress in Otolaryngology," Wednesday.

MASSACHUSETTS

Society of Psychiatry—At the annual meeting of the New England Society of Psychiatry, April 25, Dr James V May, Boston, was elected president of the society. Dr Forrest C. Tyson Augusta Maine, vice president, and Dr Harlan L. Paine North Grafton, secretary. Dr Clarence M. Hincks general director, National Committee for Mental Hygiene, New York addressed the meeting on 'Current Trends in Mental Hygiene' and Dr Felix Deutsch University of Vienna on 'Psychophysical Problems'. Dr Purcell G. Schube, Hartford, Conn. was awarded first prize in research by the society at this meeting for his article on 'Blood Cholesterol Studies in Mental Diseases'. A second prize was awarded jointly to Dr J. Kasanin and Zitha A. Rosen, Howard R. I., for their contribution to 'A Study of Clinical Variables in So-Called Schizoid Personalities'.

Historic Characters of Medicine Portrayed—Junior and senior students of Tufts College Medical School, Boston, presented a medical-historical pageant at a meeting of the Essex North District Medical Society in Newbury May 3. The following characters prominent in medical history, were impersonated by the students: Moses 1220 B. C., Galen, A. D. 130-200, Avicenna, 980-1036, Leonardo Da Vinci, 1452-1514, Paracelsus 1493-1541, Antony van Leeuwenhoek, John Hunter, 1728-1793, Claude Bernard, 1813-1878, Florence Nightingale 1820-1910, Elizabeth Blackwell 1821-1910, and Marie S. Curie, 1867. Babylonian-Assyrian medicine, 4500-2000 B. C., and the first demonstration of ether anesthesia, Oct. 16 1846 were also depicted on the program. Following the pageant there was an exhibition of Babylonian clay tablets and classic texts by the director of the Boston Medical Library, Mr J. F. Ballard.

MICHIGAN

New Low Death Rates—The lowest death rates in the history of Michigan were noted in 1932 for typhoid, diphtheria and tuberculosis. A new low level was also reached for births and deaths and infant mortality. The general death rate in 1932 was 97 per hundred thousand, the birth rate 166, diphtheria death rate 544, tuberculosis death rate (all forms), 481, and the rate for typhoid 11.

The Physician's Bookkeeper—A feature was recently added to the Detroit Physicians' Business Bureau called the Physician's Bookkeeper. Its purpose is to make available to individual physicians the benefits to be derived from scientific bookkeeping and credit management. The Physician's Bookkeeper keeps the physician's books, mails out his monthly statements and superintends the collection of accounts at a small fee. During January of this year this department handled about 2,000 accounts. The Detroit Physicians' Business Bureau was organized by the Wayne County Medical Society in 1915 as a cooperative collection and credit bureau.

Birthday Dinner to Dr. Burkart—The Mecosta County Medical Society gave a surprise testimonial dinner to Dr. John L. Burkart, health officer of Big Rapids, recently in celebration of his eightieth birthday. Guests included Drs. George L. LeFevre, Muskegon, and Frederick C. Warnshuis, Grand Rapids, president-elect and secretary, respectively, of the state medical society. Dr. Burkart was state health commissioner under the administration of Governor Ferris. He is a past president of the Mecosta County Medical Society and has served as its secretary for the last several years. For many years he was professor of pharmacology and therapeutics at Grand Rapids Medical College.

MISSISSIPPI

State Medical Election—Dr. John W. D. Dicks, Natchez, was installed as president of the Mississippi State Medical Association at its annual meeting, May 11, and Dr. Edward C. Parker, Gulfport, was named president-elect. Vice presidents are Drs. Eugene R. Nobles, Rosedale, John A. K. Birchett, Jr., Vicksburg, and Charley C. Hightower, Hattiesburg. Drs. Thomas M. Dye and Ellis L. Wilkins, Clarksdale, were reelected secretary and treasurer, respectively. The next annual session of the association will be held in Natchez, May 8-10, 1934.

MISSOURI

Health Council Established—A health council for Kansas City and Jackson County was recently organized to coordinate the work of public health agencies, in order to achieve efficiency and economy in public health work. The council of the Jackson County Medical Society cooperated with the committee on public health and welfare of the chamber of commerce and the director of health of Kansas City, the late

Dr. Calvin L. Cooper, to construct a working constitution and by-laws for the Health Council. The objectives are as follows:

- 1 To study the needs and problems in the public health field in Kansas City and Jackson County
- 2 To serve as a forum for the discussion of health problems, policies and plans
- 3 To coordinate public health activities of public and private agencies in Kansas City and Jackson County
- 4 To prevent duplication and to promote extension of public health work along preventive lines

Membership of the council is made up of representatives of official and professional organizations, civic bodies, nonofficial organizations, hospitals, and members at large. A coordinating committee will be the governing body. Eligible members must be approved by the committee before acceptance as members of the council. Mr. A. H. Jewell is secretary of the Health Council and the coordinating committee. Physician members of the committee include the following: Edward H. Skinner, chairman, Jabez N. Jackson, director of health of Kansas City, Minford A. Hanna, president, Jackson County Medical Society, George E. Bellows, chairman of health and welfare committee of chamber of commerce, Joseph T. Brennan, health officer of Jackson County, and Eugene B. Perry, president, Kansas City Medical Society.

MONTANA

Changes on Health Board—Dr. George M. Jennings, Missoula, was elected president of the Montana State Board of Health, succeeding Dr. Byron L. Pampel, Livingston. Dr. Enoch M. Porter, Great Falls, was named vice president, and Dr. William F. Cogswell, Helena, reelected secretary.

Vital Statistics—In 1932, Montana recorded new low rates for maternal and infant mortality with respective rates of 6 and 50.1 per thousand live births. A new low rate (56 per hundred thousand) was also noted for tuberculosis. The fewest deaths from scarlet fever (8) were also reported for this year. There was a decrease of 589 in registered births as compared with 1931, while the birth rate dropped from 17.9 to 16.8 per hundred thousand. A decided increase in the deaths for cancer gave the state the highest rate (94.7) it has ever recorded. Deaths attributed to diseases of the heart, the leading cause of death, totaled 856.

NEW JERSEY

Changes at Princeton—Edwin Grant Conklin, LL.D., professor of zoology at Princeton University since 1908, has retired and Edmund Newton Harvey, Ph.D., professor of physiology has been named to succeed him. Wilbur Willis Swingle, Ph.D., has been appointed to the Edwin Grant Conklin professorship of biology.

Licensure of Graduates of Foreign Schools—The New Jersey State Board of Medical Examiners adopted a resolution, April 26, regulating the admission to its examinations of graduates of foreign medical schools, in harmony with the policy recently adopted by the Federation of State Medical Boards of the United States. The applicant must have a certificate from the commissioner of education of New Jersey showing that he has had two years of premedical college work including French, German, chemistry, biology and physics, must have completed a full course in a European school in good standing with the board and must have a license to practice in the country in which his school is located and a certificate from an approved general hospital that he has served a rotating internship of one year.

NEW YORK

Awards for Medical Research—The Merritt H. Cash Prize and the Lucien Howe Prize awarded under the auspices of the Medical Society of the State of New York, were presented at the annual session in New York to Drs. Harry Hamilton Cooke, Lowville, and Julius Ferber, New York, respectively. Dr. Cooke offered an essay entitled 'A Pathological, Experimental and Clinical Study of Lipoid Deposits in the Gallbladder' and Dr. Ferber an essay on 'The Present Status of Thrombo-Angitis Obliterans with Special Reference to Its Treatment by Intravenous Injections'.

New York City

Harvey Lectures—Dr. Otto Loewi, professor of pharmacology, Medical Faculty, Karl-Franzens University, Graz, Austria, delivered the eighth Harvey Lecture at the New York Academy of Medicine, May 18. His subject was 'Humoral Transmission of Nervous Impulses'. Dr. Jack C. Drummond, professor of physiology and biochemistry, University College London, delivered the seventh lecture, April 27, on 'Recent Biochemical Studies of Liver Function'.

Hospital News—The Kate Depew Strang Clinic for Cancer and Allied Diseases was recently opened at the New York Infirmary for Women and Children. The clinic, which cost about \$30,000, was given to the hospital by Dr. Elise Strang, L'Esperance and Miss May Strang, in memory of their mother, a sister of Chauncey M. Depew. Dr. James Ewing made the speech of presentation on behalf of the donors and Mrs. Frank A. Vanderlip, president of the hospital board of trustees, the acceptance address. The clinic will have a staff of seven and is equipped with a 250,000 volt x-ray tube.

University News—Two courses in gastroenterology are offered to qualified graduates in medicine June 5 to July 31, at Columbia University College of Physicians and Surgeons. A preliminary course, given Monday and Wednesday afternoons, began Monday June 5, and a clinical and laboratory course given also on Mondays and Wednesdays, was initiated Wednesday June 7. The fee for the first is \$25 and for the second \$35. Dr. Zachary Sagal, instructor in medicine is directing the courses. —George B. Ray, Ph.D., associate professor of physiology, Western Reserve University School of Medicine, has been appointed professor of physiology and pharmacology at Long Island College of Medicine, Brooklyn. He succeeds Dr. John C. Cardwell, who retired in June, 1932.

OHIO

Personal—Dr. Robert G. Steele Melmore, was guest of honor at a dinner given by the Seneca County Medical Society, May 18, in recognition of his completion of fifty years in the practice of medicine.

Continuation Conferences—Western Reserve University School of Medicine, Cleveland, has arranged to present a two day review of recent advances in medicine, June 12-13, in cooperation with the alumni association. A limited number of topics in each division of the curriculum will be selected for brief presentation. Questions and discussions will be invited. If facilities permit, alumni of other schools may be admitted.

OKLAHOMA

Society News—Drs. Lewis J. Moorman and Henry H. Turner, Oklahoma City, among others addressed the Western Oklahoma Medical Society, Clinton, March 21, on "Diagnostic and Therapeutic Pulmonary Problems" and "Anterior Pituitary Sex and Growth Hormones," respectively.

State Medical Election—Dr. Tracey H. McCarley, McAlester, was inducted into office as president of the Oklahoma State Medical Association at its annual convention in Oklahoma City, May 15-17. Dr. LeRoy Long, Oklahoma City, was named president-elect, and Tulsa was selected as the place for the next annual session, in 1934. Official business at the meeting included the creation of honorary memberships. These would be applicable to those who had retired from active practice and on recommendation of the county medical society concerned.

PENNSYLVANIA

Society News—The Fayette County Medical Society recently appointed a committee to recommend a list of standard preparations to eliminate proprietaries and thus reduce expense in filling charity prescriptions. —Dr. Walter Freeman, Washington, D. C., among others addressed the semiannual meeting of the Association of Trustees and Medical Superintendents of Pennsylvania state and incorporated hospitals for mental diseases and defect at the Elwyn Training School, Elwyn, May 26. Dr. Freeman's subject was "Biometrical Studies in Psychiatry—Population and Death."

Philadelphia

Hospital News—A nine story addition to the Hospital of the Protestant Episcopal Church of Philadelphia was dedicated, May 6. —Dr. Charles Geschickter, Baltimore, delivered an address on "Differential Diagnosis of Bone Tumors" at the Jewish Hospital, May 11. —A new \$1,200,000 unit for the care of tuberculous patients at the Philadelphia General Hospital, completed more than a year ago, is about to be equipped and will be placed in operation early in August.

Personal—Dr. Charles H. Frazier, John Rhea Barton professor of surgery, University of Pennsylvania School of Medicine was recently made a member of the German Academy of Natural Sciences. —Dr. Norman S. Rothschild, assistant professor of surgery, University of Pennsylvania Graduate School of Medicine has been appointed chief of the tumor clinic at the Jewish Hospital. —Dr. George P. Muller was recently elected a surgeon-in-chief at Lankenau Hospital. Dr. Damon B. Pfeiffer is the other surgeon-in-chief.

Leidy's Relics Presented to Academy—Certain personal effects of Dr. Joseph Leidy, founder of American paleontology and eminent in many other fields of science, have been presented to the Philadelphia Academy of Natural Sciences as a bequest from the late Dr. Joseph Leidy II, nephew of the naturalist. The relics include an old-fashioned desk at which many of the famous studies were made, a microscope he used in studying rhizopods, drawings of shells made when he was 10 years old, his lecture pointer, tipped with a metatarsal bone from a human foot, his ivory rule, notebooks, diaries and twenty-five diplomas and certificates from institutions and societies throughout the world and a holograph letter from Charles Darwin dated March 4, 1860. Leidy was elected a member of the academy in 1845 and two years later, at the age of 24, he was elected chairman of its board of curators. From 1881 till his death in 1891 he was president.

SOUTH DAKOTA

Dr. Pohlman Goes to Creighton University—Dr. Augustus G. Pohlman has resigned as dean of the University of South Dakota School of Medicine, Vermilion, to accept an appointment, July 15, as professor and head of the department of anatomy at Creighton University School of Medicine, Omaha. Dr. Pohlman has been dean at the South Dakota school for about a year, succeeding the late Dr. George R. Albertson. He also carried a concurrent appointment as professor and director of the department of anatomy. Dr. Pohlman had occupied a similar position at St. Louis University School of Medicine from 1913 to 1929, when he began special research on deafness. In 1930 he was made research professor of anatomy, giving up his administrative duties to continue his studies of deafness (THE JOURNAL June 4, 1932 p. 1198). He will succeed the late Dr. Herman von W. Schulte at Creighton.

TEXAS

Changes in State Medical Board—Dr. Isaac A. Withers, Fort Worth, has been elected president of the Texas State Board of Medical Examiners and E. Marvin Bailey, D.O., Houston, vice president. Dr. Thomas J. Crowe, Dallas, was reelected secretary. Dr. William E. Watt, Austin, was elected a member to succeed Dr. Herschel F. Connally, Waco, and Drs. Horace C. Morrow, Austin, Marquis E. Daniel, Honey Grove, and James M. Witt, Waco, were reelected.

Society News—A symposium on cancer of the breast was presented before the Dallas County Medical Society, May 25, by Drs. Everett C. Fox, John L. Goforth, Ozro T. Woods and James M. Martin. —Dr. Eugene R. Lewis, Los Angeles, was the guest of the Dallas Academy of Ophthalmology and Otolaryngology, May 2, conducting clinics and presenting two papers, on "Physical and Chemical Aspects of Glaucoma and Progressive Deafness" and "Biochemistry as Related to Changes of the Nasal and Sinus Mucosa."

UTAH

Personal—Dr. Garland H. Pace, Salt Lake City, has been appointed superintendent of the Utah State Hospital, Provo, succeeding Dr. Frederick Dunn, who will resume private practice after twelve years' service with the institution.

VIRGINIA

Clinics at University Hospital—The annual spring clinic for practicing physicians was held at the University of Virginia Hospital, May 4-5. A symposium on malignant tumors occupied one day, speakers were Drs. Edwin P. Lehman, Tiffany J. Williams, John H. Neff, Fletcher D. Woodward, William H. Goodwin and Vincent W. Archer. Other instructors were Drs. James Edwin Wood, Jr., on digitalis therapy, Everett C. Drash, surgical treatment of tuberculosis, Lawrence T. Royster, diagnosis of respiratory diseases, and Alfred Chanutin, Ph.D., vitamins.

GENERAL

Journals Merge—The *Archives of Physical Therapy*, *X-Ray*, and *Radum and Physical Therapeutics* have consolidated, retaining the name of the former. These journals were the official organs of the American Congress of Physical Therapy and the American Physical Therapy Association, respectively. The merging of the journals was the result of the amalgamation of the two organizations into the American Congress of Physical Therapy.

Medical Veterans of World War—The annual meeting of the Medical Veterans of the World War will take place at the Eagles Club in Milwaukee, June 14, at 9 p. m. Guests

of the organization will include Surg Gen Robert U Patterson U S Army Surg Gen. Hugh S Cummung, U S Public Health Service Surg Gen Charles E Riggs U S Navy and Medical Director Charles M Griffith Veterans Administration. No papers will be presented. There will be a smoker

Winners in Safety Contest—Pittsburgh and Evanston, Ill. were named joint winners of a national traffic safety contest recently conducted by the National Safety Council. Each had successfully carried out every accident prevention activity practicable for a city of its size and each had reduced its traffic death rate by about 30 per cent. The scoring system used was as follows: accident records 50 points; accident reporting 5; traffic engineering 10; traffic law enforcement 15; child safety 10; public education 10; community safety organization 10. Massachusetts was named the safest state. A second contest covering the current year is now in progress.

Society News—Dr Oswald T Avery, New York, was named president of the American Association of Pathologists and Bacteriologists May 8 and Dr Howard T Karsner, Cleveland, reelected secretary. The next annual session will be held at Toronto Ont. March 29-30 1934.—The Catholic Hospital Association will hold its eighteenth annual convention in St. Louis June 12-16. Specialization in the hospital has been selected as the theme for the meeting.—The twentieth annual convention of the International Association of Industrial Accident Boards and Commissions will be held in Chicago September 11-15 at the Congress Hotel.

Conferences on Deafness and Education of the Deaf—Round table discussions on problems of deafness and the education of the deaf will be conducted at the University of Chicago June 26-July 28 under the auspices of the university and the American Association to Promote the Teaching of Speech to the Deaf. These conferences will be coincident with the International Summer School for Teachers of the Deaf, June 26-August 21. Sectional discussions will cover various problems of administration in common with general education; otologic problems related to deafness; special problems in the education of the deaf; psychologic problems related to deafness; physical problems related to deafness; and social service administration and the education of the deaf.

Propose Board for Certification of Gastro-Enterologists—The executive committee of the recently organized Society for the Advancement of Gastro-Enterology has approved a resolution proposing the establishment of a board for the certification of gastro-enterologists. Pointing to the success of similar boards in other specialties, the committee suggested that supervision over the specialty of gastro-enterology be carried out through a board made up of representatives of the American Gastro-Enterological Association, the New York Gastro-Enterological Society, the American Medical Association and the Society for the Advancement of Gastro-Enterology. A committee was appointed to confer with the organizations mentioned, with the following members: Drs. Edward L. Kellogg, Anthony Bassler, Stanmore L. Cash, Samuel Weiss and Gustave Randolph Manning, New York.

Changes in Status of Licensure—The Arizona State Board of Medical Examiners recently reported the following:

Dr. Harold Porter Collins, Phoenix, license revoked April 3 because of criminal record in the misuse of the U. S. mails.

The Massachusetts Board of Registration in Medicine reports the following:

Dr. Abram Robert Goodman, Quincy, license revoked April 20 because of his court conviction on the charge of conspiracy with intent to defraud.

Dr. Townley T. French, Boston, license revoked April 20 on account of his conviction in court on the charge of manslaughter.

Dr. English N. McLaughlin, Roxbury, license revoked May 25 because of his court conviction on the charge of abortion.

Dr. Joseph A. St. Angelo, Centerville, R. I., license restored May 25. The license had been suspended July 2 1931.

Typhoid in 1931-1932—A review of the occurrence of typhoid in the principal countries of the world during the biennium 1931-1932 has been published by the Health Section of the League of Nations, in *Epidemiological Reports*. The lowest rates 1 per hundred thousand or less occurred in Germany, England, Switzerland, Scotland, Norway, New Zealand, the Netherlands and Sweden. The next lowest group from 1 to 29 included Australia, Austria, Denmark, the Irish Free State, northern Ireland and the Union of South Africa. In the third group in which the rate varied from 3 to 49 were Belgium, France, Canada and the United States. Among countries with a mortality rate of more than 15 are Greece, Italy and

Portugal, but in all these countries the rate represents an improvement. In general, endemic typhoid was found to have increased in most of the countries of central and eastern Europe, considerable epidemics having occurred in Hungary and Rumania in 1932. No massive urban epidemics occurred during the period the statistics showed, although Nagasaki, Alexandria and Teheran had outbreaks that increased the mortality rates to high levels.

Medical Bills in Congress—*Changes in Status*. S. 1587 has passed the Senate amending an act entitled "An Act to recognize the high public service rendered by Major Walter Reed and those associated with him in the discovery of the cause and means of transmission of yellow fever," by including Roger P. Ames among those honored by the act. *Bills Introduced*. S. 1592, introduced by Senator Capper, Kansas, and H. R. 5697, introduced by Representative Buckbee, Illinois, propose to prohibit untrue, deceptive or misleading advertising through the use of the mails or in interstate or foreign commerce. S. 1628, introduced by Senator Capper, Kansas, proposes to regulate the importation of milk, cream and milk and cream products into the United States for the purpose of promoting the dairy industry of the United States and protecting the public health. S. 1740, introduced by Senator Vandenberg, Michigan, proposes to extend hospitalization and medical treatment at hospitals and relief stations of the United States Public Health Service to (a) officers of documented vessels of the United States who are holders of unexpired licenses of the United States Steamboat Inspection Service; (b) seamen who have served forty days or more on a documented vessel during the year preceding application for hospitalization or treatment; and (c) seamen whose wages were diminished by reason of contributions made to the fund for the relief of sick and disabled seamen. S. 1785, introduced by Senator George, Georgia, proposes to amend an act entitled

"An Act to maintain the credit of the United States Government by providing domiciliary care to persons honorably discharged from the Army, Navy, and Marine Corps of the United States where they are suffering with permanent disabilities tuberculosis or neuropsychiatric ailments and medical and hospital treatment for diseases or injuries." H. R. 5611, introduced by Representative Fish, New York, provides for the forfeiture of vessels, vehicles or other means used to transport or conceal unstamped narcotic drugs, or to facilitate the purchase and sale thereof. H. R. 5626, introduced by Representative Hoepfel, California, proposes to amend the act entitled

"An Act to maintain the credit of the United States Government" so as to provide men discharged from the Army, Navy, Marine Corps or Coast Guard for disabilities incurred in line of duty with domiciliary care when they are suffering from permanent disabilities tuberculosis or neuropsychiatric ailments, and medical and hospital treatment for diseases or injuries. The bill further provides that transferred members of the Fleet, Naval and Marine Corps Reserve and all persons on the retired list of the Army, Navy, Marine Corps and Coast Guard shall be considered as having been honorably discharged. H. R. 5700, introduced by Representative Beam, Illinois, proposes to amend an act entitled "An Act to recognize the high public service rendered by Major Walter Reed and those associated with him in the discovery of the cause and means of transmission of yellow fever" by including the name of Gustaf E. Lambert among those honored by the act. H. R. 5722, introduced by Representative Dickinson, Missouri, proposes to increase the tax on distilled spirits for nonbeverage purposes to \$5 on each proof gallon or wine gallon when below proof and a proportionate tax at a like rate on all fractional parts of such proof or wine gallon.

FOREIGN

Brussels Medical Days—The thirteenth session of the Brussels Medical Days will be held June 24-28, under the presidency of Prof. Valère Cocq. The program will be confined to discussion of syphilis in its relation to the various medical specialties. Information may be obtained from Dr. Rene Beckers, secretary-general, 141 rue Belliard, Brussels, Belgium.

Society Offers Medal—The Royal Society of Edinburgh will present a medal known as the David Anderson Berry Gold Medal and a sum amounting to about £100 in July, 1935, to the person who in the opinion of the council has recently produced the best work on the therapeutic effect of roentgen rays, according to a recent announcement. A similar award is to be presented every three years.

Cancer Study Course—A graduate course on cancer will be given at the Cancer Institute of the Faculty of Medicine of Paris, June 16-July 13, under the direction of Dr. Gustave Roussy. There will be practical demonstrations and theoretical lectures each day covering many phases of the study of cancer.

The course is offered to both French and foreign physicians and to advanced students in medicine.

Internships in China—The Peiping Union Medical College wishes to emphasize that applications for internships can be accepted only from persons with a speaking knowledge of Mandarin Chinese. Many applications are received from persons who are not thus qualified and as it takes about two months for a candidate to receive a reply, the delay is unfortunate for the student when the reply must necessarily be negative, the hospital authorities point out.

Status of Jewish Physicians in Germany—The following items were taken from recent issues of German medical journals

The executive committee of the roentgenologic society of Berlin and of the physicians' society of radiology have all resigned. The executive committee turned the commissarial work of the societies over to Prof. Walter Friedrich.

Geh-Rat Prof. Ferdinand Blumenthal, director of the Berlin University Institute for Cancer Research at the Charité, was released from office by his own request.

Dr. Hans Winterstein, professor of physiology at the University of Breslau, was granted a leave of absence.

The numerus clausus and other restrictions in the medical profession and schools regarding non-Aryans will not be applicable to illegitimate offspring who were born before the new law came into effect or offspring with one Aryan parent or two Aryan grandparents.

The German student organization (studentschaft) will accept as members only students of German (Aryan) descent and mother tongue despite their present nationalities. Germans in foreign countries, therefore, and Austrian students are completely eligible to membership.

The students must give their word of honor on application for membership that, according to their best knowledge and conscience, their parents and grandparents were of German Aryan descent.

The society of German physicians in Austria of the province of Styria, presented the government with a petition requesting that foreign Jewish physicians no longer under any circumstances receive Austrian citizenship and the right to practice in Austria. They ask that only a certain percentage of native born Austrian Jewish students in proportion to the total number of Jews in Austria be allowed to matriculate in medicine.

In all public sickness welfare institutions, German physicians should actively predominate and all Jewish physicians employed there should not in any way exceed their allotted percentage. Every member of a sickness insurance society should be asked to select an Aryan physician for treatment whenever possible.

The Egyptian government granted entry into the country and the right to practice medicine to 200 German Jewish physicians who had been dismissed from the sickness insurance companies because of the German regulations against them.

The society of all Polish financial officials at its annual convention demanded that everything German or coming from Germany be boycotted because of the "bestial and barbaric treatment of Poles in Germany." Likewise the Convention of Polish Physicians exhorted its members to boycott all German pharmaceutical products, all German medical works, all German health spas and all German bathing resorts.

The entire executive board of the Berlin Medical Society resigned. Professors Adam and von Eicken are temporarily in charge of business matters. Meanwhile no meetings will take place.

At Frankfurt-on-Main, Dr. Werner Lipschitz, professor of pharmacology at the university, was dismissed during the current semester and replaced by Dr. Otto Girndt, privatdozent in pharmacology and toxicology.

The campaign in Berlin against all non-German writings began, May 6. Among these were some obnoxious materials from the Institute of Sexual Science of Dr. Magnus Hirschfeld, which were carted away in trucks. May 10 the books which were collected from many libraries were publicly burned on the Opera Square.

The director of the Seraphim Hospital in Stockholm, Prof. Israel Hohngren, gave notice that German preparations were not to be used in the future.

At Breslau the hygienist Carl Prausnitz was not given leave of absence but rather his son, the barrister.

CORRECTION

Studies in Cretinism and Hypothyroidism in Childhood.—In the article by Dr. I. P. Bronstein in *THE JOURNAL*, May 27 the average cholesterol mentioned in the seventeenth line of the second column on page 1661 should read 330 instead of 230.

The Mechanism of Pain

Dr. David Waterson, professor of anatomy in the University of St. Andrews has published in the *Lancet* results of research on the mechanism of pain. Unlike the special senses, nothing was previously known of the tissues in which pain is excited or of the nature of the receptors. One view is that pain has no apparatus of its own but is produced by overstimulation of the fibers of ordinary sensation. But it has been shown that increase in the intensity of a stimulus causes an increase in the number of impulses that pass along a nerve fiber, altering only the intensity of the sensation and not its quality. Professor Waterson has shown that in the skin the pain apparatus is distinct from that for touch. He found that a layer of epidermis could be shaved off from the finger tips without causing pain, in spite of the fact that the terminals of the nerves of touch were divided. Microscopic examination showed in the removed epidermis the terminals of the nerve fibers and the modified epithelial cells with which they were in contact—the peripheral apparatus for touch. The pain apparatus of the skin lies at a deeper level, in the corium, and responds to a variety of forms of stimulation, such as pricks, burns and cuts. The exact nature of the apparatus is not known, but there is a plexus of nerve fibers in the corium. The passage of the point of a needle through the epidermis is painless, but pain is immediately felt when the corium is penetrated. The corium is not equally sensitive throughout, for it is well known that minute points can be found from which no pain is elicited by needle prick.

Experiments were made on other tissues. When the point of a fine needle came into contact with the brachial artery, sharp pain was immediately felt. If the point was pushed on so as to penetrate the wall of the artery, a sharp pain of a peculiar sickening character, with a feeling of nausea and faintness, was produced. Penetration of the adjacent biceps tendon produced a different sensation not so severe and without the other sensations. The pain from the wall of the artery persisted for a short time after withdrawal of the needle. It was felt mainly locally but radiated down the forearm. The pain response from veins was slight and not comparable with that from arteries. It is known that pain originates from voluntary muscle in response to contraction if the blood supply is impaired. The point of a fine needle was introduced through the skin, if possible through a pain-free spot of the corium, and pushed on into muscle, no distinct pain but a sensation of deep-seated pressure, unpleasant in tone, followed by a sensation of local stiffness, was produced. Movement of the needle point in the substance of the muscle frequently produced a sharp pricking pain. From tendons and fibrous tissue a sharp pricking sensation alone was produced. From bone and periosteum the response to a needle prick was slight. Sometimes no pain was produced even when the needle was pushed into the bone. It may be recalled that the fracture of a bone by indirect violence may produce no pain at the time. The severe pain due to fracture appears to arise from spasm of the adjacent muscles. The conclusion is that pain is not produced by nerves of other forms of sensation but has its own apparatus, mainly in the corium.

Priestley Smith

The death at Birmingham of Priestley Smith, emeritus professor of ophthalmology in the university, at the age of 87 years, removes an eminent ophthalmologist. He qualified in

1871 and at once turned his attention to ophthalmology, becoming house surgeon to the Birmingham and Midland Eye Hospital and then clinical assistant at Moorfields. In 1874 he was appointed ophthalmic surgeon to the Queen's Hospital, Birmingham. A dissertation on glaucoma gained the Jacksonian prize of the Royal College of Surgeons in 1878. He discovered that the lens enlarges progressively in old age. In 1888 he was selected to open the discussion on glaucoma at the Heidelberg congress of ophthalmology. He was the pioneer of modern knowledge of the pathology of glaucoma. His work on the subject was carried on not only during his active life but after he had retired from practice and was a model of scientific investigation in which physical experiments, histologic examinations and clinical study were combined. In 1881 he became editor of the *Ophthalmic Review*. In 1898 he delivered before the Ophthalmological Society of the United Kingdom the Bowman lecture on the Etiology and Educative Treatment of Convergent Strabismus. In 1905-1907 he was president of the Ophthalmological Society of the United Kingdom. In 1927 the American Ophthalmological Society at its congress in Quebec unanimously awarded him the Lucien Howe medal. He contributed the article on Glaucoma to Norris and Oliver's *System of Diseases of the Eye*.

Women Physicians

The number of women physicians on the medical register is now 3,391 out of a total of 55,932 names. Many of them hold important official posts. The London School of Medicine for Women has 330 medical students at present. More applications are made to the school for women to fill posts than can be supplied. Miss L. M. Brooks, warden and secretary of the school, states that the present condition is an example of the swing of the pendulum from the postwar years when the medical profession was overcrowded and women who had completed their courses and were qualified were seeking in vain for appointments. Medicine today, says Miss Brooks in a press interview, "is one of the best paid professions open to women. The prejudice which has existed, and does exist, against women practitioners is disappearing with the entry of women into all the professions and with the wider experience of life in general which they have acquired. The greater importance now attached to midwifery and gynecology is to a considerable extent due to the influence of women in the medical profession. The new social conscience with regard to maternal mortality, infant care and national health insurance which necessitates the maintenance by employers of a high standard of health in factories and shops has called for increased service on the part of women physicians and specialists. The financial depression has checked opportunities to a certain extent but women are being sought increasingly not only in big cities but also in country districts."

A Declining Birth Rate in Ireland

The universality of the modern decline in the birth rate is illustrated by the fact that in an agricultural country such as Ireland with the birth control movement sternly forbidden by the predominant church the figures tell the same tale as in England, where all these conditions are the opposite. The birth rate for 1932 was 18.9 per thousand estimated population as against 19.3 for 1931 and an average of 20.2 for the decade 1922-1931. This rate, however, is higher than that for England and Wales of 15.3 and for Scotland of 18.6. The death rate for 1932 was 14.4 against 14.5 for 1931 and also for the decade ended 1931. Infant mortality was 71 per thousand births against 69 for 1931 and 70 for the decade.

Good Health Notwithstanding Unemployment

In the house of commons Sir E. Hilton Young, minister of health, stated that a careful scrutiny of the reports of the school medical officers for 1931 showed that the condition of

the children had not been affected by unemployment. This was confirmed by inquiries in many areas during the current year. As to adults, their physical condition varied no doubt in different parts of the country but, speaking generally, it was good. Contrary to what might have been expected, it did not appear to have so far been affected by unemployment. In 1932 occurred one of the lowest death rates recorded and an exceedingly low infant mortality, while there were fewer epidemics. The health officers were fully alive to the situation and were vigilant at all times to observe any departure from the normal in their districts. These results were a tribute to our national system for dealing with the evils of unemployment and to the devotion of parents to their children.

April 26, 1933

International Meeting of Directors of Red Cross Societies

The thirteenth international session of the directors of the Red Cross societies recently held in Paris, was devoted to the study of transportation of injured persons by airplane and the organization of medical aid en route. Emergency transportation of patients and physicians by airplane is used chiefly in regions in which railway transportation is little developed for example, in Persia, Siam, Australia, Morocco and even in Sweden. Red Cross societies, in various countries, are endeavoring to promote the organization of such service wherever it is needed and are recommending apparatus of a special design universally agreed on in preference to equipment hastily constructed in the various countries. Most of the directors of the Red Cross societies are agreed that the best plan would be for each country to acquire a few airplanes specially constructed for the transportation of the injured. It is admitted, however, that such a plan might necessitate too large appropriations, since such equipment, not being utilizable for other purposes, would be used only on rare occasions. Such special equipment appears to be feasible only in regions in which it is the sole means of transportation, and where, for that reason one would not be inclined to count the cost. Dr. Achtmann, member of the international bureau of health, called the attention of the conventionists to the relatively recent use of the airplane in Persia for the transportation, during an epidemic of cholera, of physicians, nurses and supplies of vaccine, whereby it became possible to vaccinate promptly more than 400,000 Persians. It was at first planned to use army airplanes, but the difficulty is that international regulations prevent army planes from crossing boundary lines. Hence, the idea was suggested of constructing commercial airplanes in such a manner that they can be quickly transformed, in case of necessity, into transports for injured persons on stretchers, accompanied and attended by a physician. In this connection, the Swedish delegate Baron Stejneger and the Norwegian delegate, Colonel Memich, suggested that an agreement be entered into between the Red Cross Society of Norway and the Norwegian commercial air lines for the transportation of patients. The commercial air lines might be induced to equip airplanes that could be quickly transformed into sanitary planes capable of transporting a patient reclining on a stretcher. The cost of transportation might be made the same that the law allows for other means of transportation for the company concerned, in accordance with the existing tariff schedule. In accordance with this suggestion, the Red Cross of Norway granted the first year, by way of trial an appropriation of 6,000 crowns to the air transportation company selected. During the congress at Paris, a demonstration of sanitary airplanes was given at the Bourget airport with a plane belonging to the Compagnie Air-Union, a 'Rapid Azur,' of the Breguet 280 type. Under the supervision of Mr. Petersen, general secretary of the league of

Red Cross societies, the foreign delegates participated in all the maneuvers connected with the installation of the reclining patient in a special cabin within the plane, also in the take-off, and the landing. Mr. Henry Bardel, technical director of the Air-Union, explained to the delegates that all the single motored and double motored planes of his company, which controls air lines from Paris to London and Paris to Marseilles can be almost instantly transformed into sanitary planes. Since the existing flying equipment can now be placed immediately at the disposal of physicians or sanitary officers the sole question that remains is the reaching of an understanding between the Red Cross societies and the various air navigation companies with a view to securing for the use of injured persons such readily convertible planes. Mr. Petersen, general secretary, has established contacts with the International Air Traffic Association which deals with all questions pertaining to international air navigation, with the national groups of the countries interested in sanitary aviation, and with the directors of the air navigation companies of France and England. At the next congress, he will present the text of a definitive agreement.

FIRST-AID STATIONS ALONG THE HIGHWAYS

The subject of first-aid stations along the highways brought about an exchange of views. France has at present 2,000 such stations. The league of Red Cross societies, which is studying the subject of standardization, throughout the world of first-aid stations along highways has appointed a permanent committee for that purpose. The French model has served as a basis for the type of station recommended to all societies promoting the establishment of such stations. Twenty-eight national societies have already adopted the French model and eight others are considering its adoption. The French identification sign for first-aid stations which is well known to all automobilists, was likewise accepted at the Geneva conference held in 1931, as a model type to be used on the highways of all nations approving it. The league of the Red Cross societies, which serves as a secretariat for the committee, is collecting statistics on automobile accidents, including the causes, in all the countries of the world. For France, the U N A T has already collected a vast amount of statistical material, the study of which has furnished answers to the following questions: (1) the hours at which most accidents occur, (2) the number of accidents per day, (3) the number of accidents per month and (4) the causes of accidents. It was found that the most accidents occur around 6 p. m. just before the street lamps are turned on. The second most dangerous time for accidents is a short time after the lunch hour—around 3 p. m. The third most prolific hour for accidents is around 11 a. m., when vehicles are left in the streets while their owners go for lunch. The day of the week on which the most automobile accidents occur is Sunday as all have observed. Saturday is likewise to be feared, next comes Monday. Wednesday also is dangerous owing to the large number of open markets held in the provinces on that day. Scrutiny of the statistics reveals that July the first vacation month records the largest number of automobile accidents on the highways, next comes October, because of the manifestations of countryside life including the many hunting parties. As to causes the majority of automobile accidents (nearly one half) result from failure to observe the traffic regulations. Twenty per cent of the accidents are caused by other users of the highways. Inexperience or lack of skill accounts for only 7 or 8 per cent. Accidents due to undiscovered causes are about as numerous as those resulting from failure to observe the rules of the road. The accidents due to inobservance of traffic regulations may be classified, in descending order of frequency, as follows: collisions at street or road crossings driving past other vehicles or crossing in front of them excessive speed, passing at curves, poor illumination, too intense illumination too rapid descent of hills or mountains, the passing of vehicles at the top of hill crests.

BERLIN

May 1, 1933

The Congress of Internal Medicine

The annual session of the Deutsche Gesellschaft für Innere Medizin was held as usual in Wiesbaden just after Easter. The political revolution made its influence felt also at this congress. In place of Prof. L. Lichtwitz of Berlin who was chosen last year to serve as chairman, the congress was conducted by Professor Schittenheim of Kiel, the member of the directorate next in order, who will also serve as chairman at the 1934 session. In his address, he emphasized that this session marked a mile-stone in the history of the *gesellschaft*. He brought out the following significant ideas. As an important section of the German medical profession, it is the duty and the desire of the *gesellschaft* to do its part in promoting all forms of national development in order that the progress of German culture and German intellectual life may be in keeping with Germany's claim to intellectual leadership. A foreign invasion, more particularly from the East constitutes a menace to the German race. It is an imperative necessity that this menace be now suppressed and eliminated. Also before this *gesellschaft* racial problems and questions dealing with hereditary biology must receive especial consideration. The impetus that such research has received through the initiative of the chancellor of the reich and of the circles that stand back of him merits our recognition and gratitude. Eugenics and the influences of heredity must be the preferred topics for discussion at our next session. The clarification of all the questions associated with the crossing of races will require many years of study. There can be no doubt that a regeneration of a people from within constitutes the best means of preserving its true nature. Notwithstanding the severity of the measures to be adopted for the preservation of the German race and German culture the luster of the services of such men as Ehrlich, Neisser, Minakowski and von Wassermann will not be dimmed for full recognition will continue to be accorded them. We must, however, be permitted to assert that the development of these men would not have been possible without the intimate association with the German race and without the influence of the German mode of life and mode of thinking. A great genius will still be able to rise in Germany to a high position at least a little later, after the German people has recovered from the present economic depression.

In connection with the new impetus for expansion that has seized hold of our people it is pleasing to note the energetic endeavor to liberate the physician and the patient from the chains of an impracticable and not infrequently demoralized and demoralizing health insurance system and misguided social politics. The nucleus representing praiseworthy social aid will, however, be retained. With great satisfaction the National-Sozialistischer Aerztebund counts among its aims the restoration of the family physician on whom devolves the task of preserving the public health and promoting race hygiene by means of his beneficent ministrations within the family as of old. Through recognition of the "principle of accomplishment" overcrowding of the medical profession is to be prevented. The high standing of German science throughout the world is to be guaranteed by men who by reason of their origin and character, are called to be leaders and teachers of the youth of the country. It is to be hoped that thus the medical profession may soon be freed from the quacks and charlatans.

After this presidential address, the scientific work of the session was taken up. The program of the session had undergone many changes during the weeks immediately preceding its opening. Prof. E. Laqueur had withdrawn his proposed paper on "The Problem of the Suprarenals." The first main topic dealt with "Diseases of the Erythrocytes and Hemo-

globin' Hans Fischer, chemist of Munich who discussed the chemical and physiologic aspects of the problem, called particular attention to the extensive research on the porphyrins and to the established close relation between hemoglobin and chlorophyll. In severe poisonings and also in other diseases the porphyrins are excreted in the urine which takes on a dark burgundy-red color. These porphyrins, as the second speaker, Kaemmerer of Munich brought out belong to the fluorescent substances that produce sensitiveness to light. If porphyrin is administered to light colored animals such as white mice and they are then exposed to sunlight they suffer severe injuries due to the light and develop cutaneous diseases and mutilations of the extremities resulting finally in death. Many human beings with porphyrin disturbances become in this manner exceedingly sensitive to light and, in spite of avoidance of intense illumination, present severe cutaneous disturbances and mutilations of the extremities. Others are attacked by severe intestinal colic, and sometimes with ileus paralysis, delirium and the like. Kaemmerer considered the possibility as to whether some psychopathic conditions might not be found to be due to porphyrin disturbances. Seyderheim of Frankfurt-on-Main spoke on the synthesis of the blood. The functioning of the red corpuscles depends, to some extent on the supplying of a normal amount of building material in which vitamins play an important part. Disturbance of their resorption in the intestine may lead to anemia and reduction in the calcium content of the bones. In a healthy person it is the task of the gastric juices to break up food substances and to separate out such materials as are needed for blood formation. Reduction or impairment of the gastric juices will have causal importance for the genesis of progressive anemia, in which a liver substance needed for blood formation is not present in normal quantities. Hence, liver eliminates anemia temporarily, following its ingestion.

On the second day, F. Schellong the chief physician of the clinic of the chairman in Kiel delivered an address on low blood pressure. An important role is hereditary predisposition. The therapeutic indications point sometimes to rest and sometimes to physical exercise and medical treatment. Similar conditions occurring in severe disorders of the midbrain and the hypophysis arouse the thought that a hypofunctioning of those organs plays a part in low blood pressure.

The last main topic concerned the importance of the heavy metals. The first speaker was W. Heubner pharmacologist, of Berlin. The smallest living organisms require for their bodies such metals as iron, nickel and copper. The more highly developed organisms need iron for the hemoglobin and cellular respiration. A metal may act in various ways. Some heavy metals (iron and copper) accelerate certain chemical processes, particularly respiration. Aside from these necessary metals, others exert a disturbing influence on the cells through the replacement of chemical cellular components and thus develop a toxic action (silver, mercury, gold, copper, lead, zinc). Some precious metals, particularly gold and silver are used against infections. The results and the action are, however, still subjects of controversy. The clinical importance of the heavy metals was discussed by P. Martini, internist, of Bonn. The most important heavy metal from a clinical point of view is lead, and mercury follows, much more infrequent are chronic chrome, zinc, manganese, thallium, barium, bismuth, silver and gold poisoning. All heavy metals and their salts may cause poisoning through entrance into the blood stream. In comparison with poisoning caused by lead and mercury other poisonings due to heavy metals are insignificant. Manganese, however, causes typical poisoning and zinc fever is well known. The remaining clinically important metal poisonings are due almost exclusively to metals with an atomic weight above 200. It is impossible for the differences in poisonings to be based entirely on quantitative differences. There must be essential differences

in the mode of action. There is no uniform clinical conception of poisoning due to heavy metals.

A manuscript from the Zurich toxicologist Zangger, supplemented by the experiences of the speaker, Baader of Berlin followed. Often poisonings are caused not by the metals themselves but by organic compounds of preparations that arise as by-products in the processes of manufacturing, many of which do not have the appearance of metals but are oily and, in part transparent fluids. They are used on the farm or in the home and generally have a trade name, so that the layman, and even the physician, does not know their composition. A law should be enacted requiring a 'poison' label on which is given the composition of such products. In Germany, around 1,500 cases of lead poisoning are notified annually, strange to say, only 0.2 per cent of the cases originate among printers, so that the belief that printers are especially endangered is no longer justified. Lead poisoning among artists is now relatively rare. Since the enactment in 1925 of a law granting compensation for industrial poisoning due to metals there have been numerous cases of simulation. Baader stated that it is possible to establish beyond doubt in which cases the symptoms are genuine and in which cases they are simulated.

ITALY

March 31, 1933

Meeting of Academy of Sciences

The Accademia Pugliese di scienze held its regular session in Bari, under the chairmanship of Professor Gaetano Trincherà reported the results of research on the gallbladder following ligation of the cystic duct either with or without ligation of the vessels. A similar operation was done on a normal gallbladder after provoking an acute cholecystitis. Blocking of the cystic duct was done from time to time either with a full gallbladder or following its evacuation. After blocking of the duct with the cystic vessels, the speaker observed almost total and complete atrophic sclerosis of not only the gallbladder but also the hepatic bed. A similar observation was made on the gallbladder with provoked acute cholecystitis. If, on blocking of the cystic duct, the artery and the vein are left intact the changes produced are much slighter. From his experimental results the speaker drew deductions that possibly apply to man. Cetroni discussed three theories in regard to the association of tuberculosis with endometriosis, namely that the association is casual, that the diffusion of tuberculosis is facilitated by endometriosis, and that the tuberculosis stimulates the mucosa and brings about an invasion of the myometrium. None of these views can be rejected a priori. Some cases that were observed tend to support the fundamental importance of tuberculosis in the genesis of endometriosis.

Milella discussed variations in the blood proteins following the introduction of sodium chloride. He observed that after large doses of sodium chloride have been injected into the veins of dogs these electrolytes become strongly fixed in the liver and a disturbance of the protein equilibrium of the blood results, with an increase of the globulins and a decrease in the albumins.

Ferrannini spoke on pneumosclerosis that develops in workers in sulphur. He demonstrated that the granules of sulphur are never destroyed by phagocytes and that the inhalation of powdered sulphur causes a hypercalcemia that is regarded as characteristic of pneumosclerosis. He described the symptoms observed in forty sulphur workers and the relative radiologic manifestations. He noted in the acute forms a desquamative pulmonitis, and in the subacute forms a slight reaction of the connective tissue which is much more evident in the chronic form. The speaker concluded that the sulphur dust is capable of causing a pneumosclerosis the signs of which are found with great frequency in sulphur workers.

Research on the Blood Vessels

Luisada of Naples carried out research on the isolated blood vessels, studying the electrical phenomena that are produced in isolated arteries and veins, spontaneously and also when they are subjected to rhythmic interruptions of the blood flow. The isolated vessels, and particularly the veins, furnish important electrical complexes, as Luisada has announced to the Academy of Sciences in Naples. The speaker described also the slow electric waves that accompany the variations in the form of the walls. By means of pharmacologic experiments, Luisada showed that biologic currents are involved. The slow waves appear to be "tonic currents" and the rapid waves "action currents."

The speaker sought to discover whether his deductions are applicable to the normally pulsating arteries. By means of a special apparatus, and grafting an arterial stump into another living artery, the speaker found that every electrical phenomenon disappears completely after suturing of the stump. Luisada concluded that the blood does not furnish appreciable currents of a physical nature as it flows through the arteries, and that, in all probability, all the electrical phenomena presented by a living artery are of a biologic nature.

RIO DE JANEIRO

Symmetrical Lipomatosis

The *Brasil-medico*, in its March 18 issue, published an article by Dr. Joaquim Moreira da Fonseca, assistant to the Medical Clinic of the Faculty of Medicine of Rio de Janeiro. He says that symmetrical lipomatosis may be general or local (cervical and thoraco-abdominal). The tumors are symmetrical, diffuse, round or oval, varying in size from that of a hen's egg to that of a large orange, painless, soft, movable, nonadherent to the skin and of more or less rapid growth. They are found in the neck, thorax, abdomen and lower limbs, being less common in the thoraco-abdominal region. In the neck the lipomas form a thick collar, giving to the cephalic extremity the appearance of a truncated pyramid with its base at the lower end, in the thoraco-abdominal localization there is a pseudogynecomasty, and in the abdominal region there are four large adipose pendulous tumors separated by a double groove in the form of a cross, the intersection of which is found over the umbilicus. There is a variety called by Roch discrete lipomatosis in which the lipomas are numerous (from ten to fifty), circumscribed, localized on the forearms, thighs and waist, without perfect symmetry; these have a predilection for the male sex, arise during infancy and adolescence and have a slow and, at times, regressive evolution. Symmetrical lipomatosis predominates much more in men than in women and appears generally during the period of the change of life. The etiology is obscure and does not present a hereditary or familial character; alcoholism is present in a large proportion (40 per cent). The pathogenesis is not clear, its ganglionic origin recognized by Launois and Bensaude cannot be accepted, except in a small number of cases. The cutaneous theory of Unna and Gräsch is also faulty. The theory of the influence of the glands of internal secretion seems more plausible, especially that of the hypophysis through a hypofunction of its posterior lobe. The part played by the sympathetic nervous system is undoubtedly important. Symmetrical lipomatosis may be qualified as an "endocrinopathic syndrome." As to the medical treatment, preference is to be given first to hypophyseal, then to genital and, lastly, to thyroid opotherapy, besides diet and physical therapy. Surgical treatment is justified when the lipomas are a nuisance but is compulsory when they produce dyspnea, dysphagia or cerebral ischemia on account of their location in the neck. The operation is delicate but not dangerous.

Cutaneous Leishmaniasis

In the January issue of the *Anuário paulista de medicina e cirurgia* of São Paulo, Dr. J. Mattos Barretto describes the two distinct clinical features of cutaneous leishmaniasis, Oriental boil and American leishmaniasis, and states that, being primarily an infection of the skin, leishmaniasis manifests itself only secondarily in the mucous membranes of the upper respiratory tract. He points to the noneffectiveness of the general treatment by antimonial and arsenical preparations in a great percentage of cases. He describes diathermic fulguration and superficial diathermic coagulation by modern high frequency apparatus. Their disrupting and coagulating action, being moderate, superficial and circumscribed spares the underlying tissues, which are always left with sufficient vitality for regeneration, and their sterilizing and hemostatic action prevents dissemination of infection through the blood and lymph vessels. The apparatus consists of the directoscope of Haslinger and the electrode of Poyet. Embrocations with methylene blue (methylthionine chloride U. S. P.) are used after the applications. Instillations of mentholated oil are indicated until the falling of the crust from eight to ten days later. If necessary, another application may then be made. On thirty-seven observations from January to June, 1932 in the service of Prof. Paula Santos, the author has obtained fourteen cures, confirmed by biopsy and histologic examination.

He concludes that diathermic fulguration and superficial diathermic coagulation constitute a valuable method in conjunction with the general treatment by antimonial and arsenical preparations.

BUDAPEST

(From Our Regular Correspondent)

April 29, 1933

The Payment of Fees

Recently the Budapest Medical Casino held a special meeting to discuss ways and means for physicians to collect their fees. Most doctors regard it as below their dignity to sue for their fees. This is wrong, in the opinion of prominent members of the Hungarian medical profession. There is not a doctor who would not attend poor patients gratis, but it is unfair that well-to-do patients should not pay the fee of the physician. The president of the meeting proposed that physicians should be paid for each visit and consultation, respectively, and that fees are due immediately after the termination of the attendance. If the patient does not pay his bill within a month, he should be warned in a registered letter, and then if he fails to pay, he should be sued. Then it will not happen that families of physicians will be exposed to poverty and misery. They also resolved that specialists and operating surgeons should not begin a long treatment without the patient paying in advance at least one third of the agreed sum.

Graduate Medical Teaching

The economic situation has affected also graduate medical teaching. Village doctors cannot afford the expense connected with living in the capital for from two to four weeks and the state is unable to grant as many subsidies as it did in former years. In 1930, 933 physicians were granted full subsidies for the duration of the courses but in 1931 only 479 physicians could be granted subsidies and in the following years still less. To make it possible for urban physicians to attend graduate courses, Prof. Emil Grosz, president of the Central Committee of Postgraduate Teaching, made arrangements that courses be held also in larger towns and cities. If there are no competent lecturers in the rural towns, the central committee appoints university men to hold the lectures. Owing to the financial situation, further reductions of the budget threaten. In spite of this, the central committee continues the graduate teaching of physicians, which is more needed than ever. The

ministry of welfare has erected the House of Physicians, where country physicians can have free board while attending graduate courses. Last year, eighty-two physicians had free board and hundreds of others enjoyed board at highly reduced rates. During the courses last year, about one third of those in attendance were foreigners.

Two Budapest Professors Honored

The medical faculty of the University of Lyons France has appointed Dr. Alexander Koranyi professor of internal medicine at the Budapest University, and Prof. Dr. Emile Grosz professor of ophthalmology and president of the International League for the Campaign Against Trachoma, as honorary physicians. The ceremony was held with great solemnity in March.

A New Medical Monthly

Under the able editorship of Dr. Vilmos Muller, counselor to the royal court, a monthly paper with the title *Nepvedelem és Tuberculosis* (The Protection of the People and Tuberculosis) was launched in April. The new monthly will deal particularly with tuberculosis, with special reference to prevention.

Roentgenologists Refuse to Take Part in Congress in Germany

Hungarian roentgenologists who are members of the German Roentgen Society received a circular letter from Vienna saying that Professor Kienbock, the pioneer of roentgenology, resigned from the position of president of the congress to be held in Bremen this summer and that neither he nor the Austrian members of this society will go to the congress. The resignation of Professor Kienbock followed preliminaries that were unprecedented in medical history. Professor Kienbock's scientific fame is known all over the world with Professor Holzknecht he founded the Vienna Roentgen school.

The secretary of the German Roentgen Society sent a polite letter to Professor Kienbock, informing him that they have to adjust themselves to the general German political situation and to see that the officers and lecturers of the congress are exclusively of Aryan race.

Professor Kienbock is the brother of Dr. Otto Kienbock, a leading member of the Austrian Christian-Socialist party, several times member of the Austrian government and now president of the Austrian National Bank. This, however, was insufficient, in present German eyes to be president of a German society, because the mother of the Kienbock brothers was of Jewish descent.

Kienbock sent the letter to the Austrian Roentgen Society, whose members decided unanimously that among such circumstances they do not wish to partake in the Bremen congress.

Moreover, two prominent Vienna professors, Dr. Arthur Schüller and Dr. Gottwald Schwartz, both have withdrawn their contributions. Likewise a well known Hungarian roentgenologist canceled his lecture.

The Hungarian Roentgen Society emphasized that its withdrawal from the congress was only an act of solidarity among its members.

The Journal

The *Orvos Szóvetség*, a Hungarian medical journal in a recent issue devotes three pages to a description of the American Medical Association and THE JOURNAL. The article extols the work of the Association, saying that the Association is idealistic and fulfils its duty in the most perfect way. To its great merit, it has built up a professional standard that is not surpassed in any country of the world. In this noble effort it is greatly assisted by its official paper THE JOURNAL, which, it may be said is the best medical weekly paper in the world. It is edited in an exemplary way, and its columns represent the best that medical literature can offer. One who peruses its articles can dispense with all other medical journals.

Marriages

LAWRENCE LINCOLN BEALL, Durham, N. C. to Miss Virginia Graham McLean of Cleveland, Miss., April 16.

GRANT E. METCALFE, Brodheadsville, Pa., to Miss Evelyn Rose Steele of South Bend, Ind., May 6.

CEDRIC CAESAR CARPENTER, Summit, N. J., to Miss Ottilie Elisabeth Schreiber of New York, May 6.

WILMORE R. SHERRICK to Mrs. Helen Crouch Long both of Richmond, Va., March 25.

HAWES CAMPBELL, JR., to Miss Ellen James Hudgens, both of Richmond, Va., April 14.

IRWIN CLAY HANGER to Miss Sarah Baldwin, both of Cleveland, April 8.

Deaths

William Thomas Councilman, for thirty years Shattuck professor of pathological anatomy Harvard University Medical School, Boston, died suddenly, May 26, of heart disease at his summer home in York Village, Maine. Dr. Councilman was born in Pikesville, Md. Jan. 1, 1854. He received his M.D. from the University of Maryland School of Medicine, Baltimore in 1878, studied at universities in Vienna and Leipzig, and received honorary degrees from Harvard, Johns Hopkins, Maryland and McGill universities. He was associate and associate professor of pathology, Johns Hopkins University, 1886-1891 and in 1892-1922 Shattuck professor of pathological anatomy Harvard University Medical School. In 1904-1909 he was a member of the Council on Medical Education of the American Medical Association, and in 1909-1917 a member of the Board of Trustees of the Association. He was a fellow of the American Academy of Arts and Sciences and the Philadelphia Academy of Medicine, a member of the Massachusetts Medical Society, National Academy of Sciences, American Association of Pathologists and Bacteriologists, American Physiologic Society and the American Philosophical Society. He was the author of *Pathology A Manual for Teachers and Students*, and monographs on dysentery, cerebrospinal meningitis, diphtheria and smallpox.

John Leo Sagerson, Loretta, Pa., Medico-Chirurgical College of Philadelphia 1898, member of the Medical Society of the State of Pennsylvania, past president of the Cambria County Medical Society, at one time member and president of the board of health of Johnstown, aged 64, formerly on the staffs of the Conemaugh Valley Memorial Hospital and the Mercy Hospital, Johnstown, where he died, April 23, of cerebral hemorrhage.

William Madison Gay, Saranac Lake, N. Y. University of Pennsylvania School of Medicine Philadelphia, 1899, member of the Massachusetts Medical Society, supervisor of veterans' administration facilities, served during the World War, aged 59, died May 13 in the Veterans Administration Hospital, Sunmount, of coronary thrombosis.

Winthrop Allen Risk of Washington, D. C., Harvard University Medical School, Boston 1893, member of the Rhode Island Medical Society, resident physician to the Tuberculosis Hospital of the District of Columbia, aged 64, died May 1 of peritonitis as the result of perforated diverticulum of the intestine.

William Hyde West of Woodstock, Ill., Hahnemann Medical College and Hospital, Chicago, 1911, fellow of the American College of Surgeons, formerly secretary of the McHenry County Medical Society, surgeon to the Woodstock Hospital, aged 47, died, May 11, of injuries received when he fell from a horse.

Henry Zeigler Hissem of Ellsworth, Kan., Bellevue Hospital Medical College, New York, 1883, formerly member of the state board of medical examiners, member of the Radiological Society of North America, on the staff of the Ellsworth Hospital, aged 75, died May 4 of cerebral hemorrhage.

John William Bailey of Seattle, University of Minnesota Medical School Minneapolis 1894, McGill University Faculty of Medicine, Montreal Que. Canada 1895, aged 63, died suddenly, May 1, at the Providence Hospital, of bilateral pulmonary thrombi and hypernephroma of the right kidney.

Carlton Nelson Russell, Philadelphia, Temple University School of Medicine, Philadelphia 1907, Medico-Chirurgical College of Philadelphia, 1911, also a dentist, professor of oral

surgery and anesthesia, Temple University, served during the World War, aged 57, died May 12, of heart disease

Joseph M A Gravelle, St Paul, School of Medicine and Surgery of Montreal, Que Canada, 1892, served during the World War, aged 63, died, March 31, in the Veterans Administration Hospital, Fort Snelling, of cardiac decompensation and coronary disease.

Fred James Hatch, Kansas City, Mo., University Medical College of Kansas City, 1907, member of the Missouri State Medical Association, served during the World War, aged 54, on the staff of St Mary's Hospital, where he died, March 31, of retroperitoneal sarcoma

Alonzo Clarke Vandine, Charleston, W Va Louisville (Ky.) Medical College, 1898, member of the West Virginia State Medical Association, formerly member of the state legislature, at one time mayor of Clendenin, aged 60, died, May 2 of coronary embolism

Herbert Chester Edward Meyer, Sioux Falls, S D., University of Minnesota Medical School Minneapolis, 1925, member of the South Dakota State Medical Association, aged 35 died April 16, at Rochester, Minn., of carcinoma of the rectosigmoid

Guy Robert McCreery, Hugoton, Kan., College of Physicians and Surgeons, Medical Department Kansas City University 1902, veteran of the Spanish-American and World wars, aged 55, died, April 15, in a hospital at Wichita of endocarditis

Serafino F Chiarulli, Syracuse N Y Regia Università di Napoli Facoltà di Medicina e Chirurgia, 1901, member of the Medical Society of the State of New York, on the staff of the Crouse-irving Hospital, aged 59, died, April 29, of pneumonia

Leonard A Saxer ♂ Syracuse, N Y, Syracuse University College of Medicine, 1882, formerly member and past president of the board of education, aged 76, on the staff of the Hospital of the Good Shepherd, where he died, May 1, of pneumonia

Samuel Franklin Klesner, Flint, Mich., George Washington University School of Medicine Washington D C, 1932, aged 29, intern at the Hurley Hospital, where he died, March 30, of pneumonia following an operation for appendicitis

Francis B Ricketson, Warrenton, Ga., University of Georgia Medical Department Augusta, 1887, member of the Medical Association of Georgia, formerly member of the state legislature, aged 73, died, March 26, of heart disease

John Elmer Heslop, Beaverton Mich., Queen's University Faculty of Medicine, Kingston, Ont, Canada, 1887, served during the World War, aged 68, died, April 28, in the General Hospital Saginaw, of carcinoma of the prostate

Frank Hamilton Towne, Niagara Falls N Y University of Buffalo School of Medicine 1909, member of the Medical Society of the State of New York, aged 46, died in May, at the Memorial Hospital of heart disease and arthritis

Violet Palmer Brown, Kankakee, Ill., Northwestern University Woman's Medical School, Chicago 1898, aged 57 died May 16, in the Wesley Memorial Hospital, Chicago, of carcinoma of the liver and diabetes mellitus

Percy Alexander Riddler, Fort Smith, Ark., University Medical College of Kansas City, Mo., 1908, member of the Arkansas Medical Society, served during the World War, aged 54, died, April 30, of angina pectoris

Joseph Frank Fleming, Trout Run, Pa., College of Physicians and Surgeons Baltimore 1884, member of the Medical Society of the State of Pennsylvania, aged 72, died, April 23, of lobar pneumonia and myocarditis

Lawrence Edward McDaniel, Jackson N C University of Maryland School of Medicine Baltimore 1911, aged 52 died May 3, in the Roanoke Rapids (N C.) Hospital, of acute cholecystitis and bronchopneumonia.

Clarence Sumner Brigham, Leominster Mass., University of Vermont College of Medicine Burlington 1891, member of the Massachusetts Medical Society, aged 66, died, May 4, of asthma and coronary sclerosis

Norman Dreisbach ♂ Minneapolis St. Louis College of Physicians and Surgeons 1894, aged 65, died April 29 in the Minneapolis General Hospital of cerebral hemorrhage, arteriosclerosis and bronchopneumonia

Dow Taylor, Supply, Okla., Memphis (Tenn.) Hospital Medical College, 1900, member of the Oklahoma State Medical Association, aged 58 died March 8, of cerebral hemorrhage and chronic myocarditis

Clinton H Ives ♂ Dixon Ill., Northwestern University Medical School Chicago 1894, past president of the Lee

County Medical Society, aged 66, died, May 15, at Akron, Ohio, of heart disease.

Everett A Hoyt, Bay City, Mich., University of Michigan Medical School, Ann Arbor, 1881, member of the Michigan State Medical Society, aged 74, died, April 28, of cerebral hemorrhage

Alfred K Scholl, Philadelphia Jefferson Medical College of Philadelphia, 1885, member of the Medical Society of the State of Pennsylvania, aged 65, died, May 7, of carcinoma of the bladder

Charles E Giles, Chicago, Howard University College of Medicine Washington, D C 1907, aged 50, died, March 5, in the Chicago Municipal Tuberculosis Sanitarium of tuberculosis

Walker Eugene Stallings ♂ Denver, Vanderbilt University School of Medicine Nashville, Tenn 1920, member of the Idaho State Medical Association, aged 37, died, May 6

Katharine A Williamson, Philadelphia Woman's Medical College of Pennsylvania, Philadelphia, 1887, aged 79, died April 18, in the Woman's Hospital, of cerebral hemorrhage

B Arthur Middleton, Emmerton, Va., College of Physicians and Surgeons, Baltimore, 1877, member of the Medical Society of Virginia, aged 77; died April 3, of heart disease

Hurbie Andrews Taylor, Stonewall N C., University of Alabama School of Medicine, 1912, formerly member of the state board of health, aged 42, died, April 13, of heart disease

John Hansford Thomas, Greenville, Va., Baltimore Medical College 1896, member of the Medical Society of Virginia, aged 60, died, February 1, of cardiovascular renal disease

Horatio G Lane, Blanket, Texas, Memphis (Tenn.) Hospital Medical College 1900, aged 71, died April 19, in a hospital at Brownwood of myocarditis and nephritis

Joseph Freeman Hughes, Smackover Ark (licensed, Arkansas, 1903), formerly member of the state legislature, aged 69, died April 2, of cerebral hemorrhage.

Phil S Henderlite, Pacific Beach Wash Barnes Medical College, St. Louis, 1905, also a druggist, aged 70, died, March 11, in Aberdeen of chronic myocarditis

Antheme Dutilly, Montreal Que., Canada, University of Montreal Faculty of Medicine, 1920, on the staff of the Hospital of St Justine, aged 42, died, February 22

Orthello Waters, Long Beach, Calif., Chicago Physio-Medical Institute, 1886, aged 72, died April 6, of arteriosclerosis, cerebral thrombosis and myocarditis

John E Moore, Shiloh, Ohio, College of Physicians and Surgeons Baltimore, 1890, aged 75, died April 6, of arteriosclerosis and chronic myocarditis

Owen W James, Detroit, Meharry Medical College Nashville, Tenn., 1889, aged 64, died, April 24, in the Harper Hospital of military tuberculosis

William H Hanes, San Angelo, Texas, Baylor University College of Medicine, Dallas, 1915, aged 47, died, April 30, of pulmonary tuberculosis

Robert Grenville Day, St. John N B, Canada, University of Pennsylvania School of Medicine, Philadelphia, 1892, aged 77, died recently

Marcus Offutt Kagy ♂ Chicago University Medical College of Kansas City Mo 1911, aged 47, died, May 9, of perforated duodenal ulcer

James Obed Calkin, Sackville, N B Canada University of Vermont College of Medicine, Burlington, 1890, aged 73, died March 22

John Victor Anderson ♂ Fairview, Okla., Kentucky School of Medicine, Louisville, 1907, aged 57, died, May 7, of encephalitis

Alexander Boucher, Loretteville, Que., Canada Laval University Faculty of Medicine, Quebec, 1886, aged 74, died, February 17

Horace G Jones, Medaryville Ind., Medical College of Indiana, Indianapolis, 1886, aged 74, died, April 9, of heart disease.

William Walter Hartman ♂ Los Angeles Rush Medical College, Chicago, 1923, aged 32, died, April 25, of a gunshot wound

Harry T Hopewell, Strasburg Va., Maryland Medical College, Baltimore, 1903, aged 56, died, March 18, of paralysis

John Allen Nelson, Owensboro, Ky., Hospital College of Medicine, Louisville, 1898, aged 70, died April 20, of uremia

C W Goodrich, Wichita Kan., Physio-Medical College, Cincinnati, 1874, aged 91, died, April 17, of heart disease.

Bureau of Investigation

BANBAR

Another Nostrum for Diabetes

Recently in the federal courts in Pittsburgh a case was tried against one Leo Banks Barlett, an ex-shirt salesman, who manufactured and exploited a product called 'Banbar,' as a cure for diabetes. The government chemists analyzed Banbar and reported that it was a water-alcohol mixture flavored with oil of peppermint and containing considerable vegetable extractive, with epsom salt, potassium acetate, uva ursi (bearberry), podophyllum strychnine, brucine leptandra and equisetum (horsetail). The advertising would lead the diabetic to believe that by using this mixture, he could discontinue insulin and for all practical purposes eat anything that he wanted.

The government was assisted in its case by a number of reputable physicians who testified as experts relative to the worthlessness of a preparation of the character of Banbar. Most of them testified, also, to treating patients who had come to them after using Banbar without results.

The exploiter of the 'patent medicine' on the other hand was assisted by Dr. Frank L. Doering of Pittsburgh and Dr. N. F. Phillips of Mount Lebanon Pa. Dr. Alexander Lowy, professor of organic chemistry at the University of Pittsburgh, appeared as the Banbar's chemistry expert. The Banbar concern also put on as one of its witnesses Clyde H. Campbell, a commercial chemist who is also connected with the Pennsylvania State Department of Agriculture.

The government unfortunately lost its case against this pernicious piece of quackery. The favorable verdict for Barlett may have been due to

the unusual charge made by the court at the time the case went to the jury. Barlett's lawyers submitted to the judge, at the time he made his charge to the jury certain points that they wished the judge to bring to the attention of the jury. One of these points read:

That if the jury believes that the defendant has received a large number of testimonials from individuals and from medical doctors to the effect that the remedy Banbar had helped them in their diabetic ailment and if the jury further believes that the defendant relied upon these testimonials then the defendant should be acquitted.

The judge affirmed this point suggested by Barlett's attorneys but rejected the others. This meant, in effect, that if Barlett could produce—as he did produce—testimonials from laymen or uncritical or unscientific physicians and could persuade the jury that, in making his claims for his 'patent medicine' he relied on these testimonials, then he was not guilty of fraud even though he was exploiting a product that was utterly worthless for the purpose for which it was sold.

The government lost its case, it would seem not because of any inability to prove the worthlessness of Banbar and the falsity of the claims made for it—for both its worthlessness and the falsity of the claims made for it seem to have been demonstrated—but because, under the law, the prosecution was compelled to prove *fraudulent intent* on the part of the manufac-

turer. The "patent medicine" interests knew what they were about when they brought pressure to bear at the time the Sherley Amendment to the National Food and Drugs Act was under consideration. It will be remembered that they persuaded Congress to change the original phrase of the amendment, "false or misleading," into 'false and fraudulent'.

If the courts generally take the attitude that was taken in the Banbar case, it will be practically impossible to control the sale of even the most vicious and dangerous of nostrums because it will be virtually impossible to prove fraud, which is essential if a conviction is to be brought in cases involving questions of therapeutic claims. Any one conversant with the disreputable "patent medicine" trade knows how easy it is to obtain testimonials, not only from ignorant laymen, but also from unthinking, careless or venal physicians. If the mere possession of such testimonials is going to be accepted as *prima facie* evidence of lack of fraudulent intent on the part of the 'patent medicine' exploiter, then the public will have little protection against the wiles of the quack and nostrum vender.

Correspondence

MALARIA TRANSMITTED BY HYPODERMIC NEEDLE

To the Editor—The transmissibility of malaria by means of a contaminated needle has been repeatedly corroborated since the case of Baccelli quoted in the literature of twenty-five and thirty years ago, e. g. Marchiafava and Bignami (Twentieth Century Practice), Mannaberg (Nothnagel's System, vol. Malaria). In recent years, since the treatment of dementia paralytica by injecting malaria blood has come into use, several instances of transmission by minimal traces of blood have been noted and commented on. With respect to the case report by Oliver C. Nickum (THE JOURNAL, May 6, p. 1401), the evidence is insufficient and the conclusion unjustified that any of the patients referred to had a malarial infection at this time and if so that the supposedly contaminated needle played any part in it. At least this much comment is in order. Most of the evidence is hearsay from patients, no definite history of malaria is made out and previous repeated negative observations at a hospital throws doubt on the supposed finding of 'organisms of the tertiary [sic] type.' The hypothesis of a reactivation mentioned is fanciful and contrary to the established proof that residual malaria protects against infection with the same strain of parasite. A period of incubation of three days following the use of a supposedly contaminated needle cannot be accepted even as a possibility.

WILLIAM KRAUSS, M.D., Twenty-nine Palms, Calif

DANGER TO HANDS FROM BROKEN TAPS

To the Editor—Within the past two years we have been called on to treat five cases of severe lacerations of the palm of the hand caused from porcelain tap handles. In each instance the history given was that the tap handle suddenly broke as the water faucet was being turned on or off. A sudden striking of the faucet with the palm of the hand caused a breaking of the handle and the palm was cut against the sharp jagged portion of the handle that remained attached.

These lacerations were all deep and involved the palmar arch, causing profuse bleeding. In one case a terminal branch of the ulnar nerve was cut, resulting in a permanent paralysis of the portion of the hand supplied by that nerve. In the most recent case the cut was deep enough to sever the superficial and deep flexor tendons supplying the fourth and fifth fingers, necessitating a tedious repair.

These porcelain tap handles apparently undergo some crystallization which makes them more easily broken some time after

installation than when new This is merely our conjecture We should like to know whether others are having the same experience with palm injuries from this source

JOHN M SIMPKIN, M D, Marshfield, Ore.
RUSSELL KEIZER, M D, North Bend, Ore

THE LOW COST OF BEING SICK

To the Editor—So much has been said on the other side of this question that a brief notation of two cases on the low cost of being sick in a hospital I thought might be read with some sense of relief, so I am submitting them for publication

The Foundling Hospital in Dublin as is well known, has a worldwide fame for the practice and teaching of obstetrics When I visited this hospital I was utterly amazed at the simplicity of the building and the equipment of this famous institution It was very efficient, very clean and very homelike Only recently I noted in THE JOURNAL that Dr Bethel Solomons of this hospital after an extensive visit to the United States, was asked to give his impression of American hospitals He replied to the effect that they were far too elaborate and expensive and that with simpler equipment and far less equipment the Irish hospital did as good work as those in any other part of the world And does not the record of this hospital bear out this statement?

Another instance

On a short visit to the ancient and historic town of Blois in the southwestern part of France I took occasion to call on Dr Olivier, a well qualified neurologist who conducts an excellent sanatorium for nervous diseases on the outskirts of that beautiful little city I found that Dr Olivier was mayor of the town, and as I was leaving he advised me to have myself elected mayor of my city assuring me that the duties of the office afforded an excellent mode of recreation Besides the main building the sanatorium consisted of about half a dozen small cottages, clean and attractive with beautiful surroundings of trees and flowers One particular cottage contained about half a dozen women patients, mostly cases of senile dementia and involuntional melancholia, cared for by Sisters The doctor told me that the monthly charge for patients in the cottage was 900 francs (\$36)

I do not have the exact figures as to the cost of keeping patients in the Foundling Hospital, but I am sure it would be much less than in similar hospitals in this country As to Dr Olivier's hospital the cost is amazing being less than one-fourth that in a similar institution in this country

THEODORE DILLER, M D, Pittsburgh

DEHYDRATION IN EPILEPSY

To the Editor—Dr Fay's communication (THE JOURNAL, May 6, p 1450) apropos of the article "Dehydration in Epilepsy" (Fetterman, J L, and Kumin, H J THE JOURNAL, April 1 p 1005) constitutes a splendid restatement of the concept which he has ably developed In it, however, "dehydration" is relegated to a position as an adjunct in the treatment, whereas, in earlier writings, dehydration is the essential therapeutic measure based on "the mechanical theory of epilepsy" The aim of treatment is to improve cerebral circulation Yet if it could be shown that there was a significant improvement in cerebral circulation, would it benefit a sensitive area in the cortex due to a congenital defect, scarred by birth trauma, or affected by encephalitis in infancy? Or would such improved circulation alter, in idiopathic cases, the factor of sensibility to convulsions, which though intangible, is the vital factor in epilepsy?

The improvement reported from Fay's program may not necessarily result from improved circulation. One must not overlook the reaction from encephalography, the possibly meta-

bolic influence from the change in diet, and the not negligible psychotherapy accruing from a long period of hospitalization Improvement from a procedure may reflect praise to the man as well as proof of the method.

Fay is right in stating that our work did not duplicate his entire program He stresses the harm of limiting fluids to 100 cc a day, stating that the optimum is 600 cc. We did not limit the fluid to 100 cc we reduced it by 100 cc. until from 400 to 600 cc was reached. Further, the communication discounts the inference from a too brief study of several weeks Though some of our patients were observed in the hospital for only three to five weeks, the majority were studied as ambulatory patients from three to twenty-two months

As regards the question of weight, seven of the nine hospitalized patients lost each from 2 to 9 pounds in about an interval of two weeks The ambulatory cases were not checked for weight loss

The article by Dr Kumin and myself was merely a report of our experience with an everyday trial of limiting fluid intake among patients with chronic epilepsy It claimed no more.

JOSEPH L FETTERMAN, M D, Cleveland

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request

TREATMENT OF SUBACUTE BRONCHITIS

To the Editor—Will you please discuss the treatment of acute and subacute bronchitis with drugs particularly the use of ipecac ammonium chloride terpin hydrate creosote and its newer derivatives Physicians everywhere are constantly deluged with drug salesmen and advertising literature in an effort to induce them to use this or that cough preparation I feel that a straightforward discussion of this topic would be timely and valuable and perhaps help to purge most of these shotgun preparations from the drug shelves of the practitioner's office

EDGAR S LEEUC M D, McConnellsburg Pa.

ANSWER—In the treatment of a cough it is necessary to distinguish between the useful and the useless cough Only in the latter are the antitussics, such as codeine, indicated It may be taken as an axiom that, the less of cough "killers" one prescribes in bronchitis, the better for the patient The problem here is to improve drainage from the affected mucous membrane to rid it of infection, to improve its nutrition and thereby favor healing, and to improve the patient's resistance to infection As long as the cough is 'tight,' softening the expectoration should be the aim, for this purpose, water is the chief agent. The so called expectorants, without water, usually fail though water given alone may also be futile All that expectorants can do is to favor excretion of some of the ingested water by way of the bronchial tree. Of the absorbable salines, ammonium chloride and potassium citrate deserve chief consideration in acute bronchitis The former, given freely (0.3 Gm with an abundance of water every hour) is the more potent, but because of its tendency to acidify the system, it should not be used in the presence of a considerable amount of fever, with its tendency to acidosis In such conditions, potassium citrate (from 1 to 2 Gm in a glassful of water every hour or two) might be the remedy of choice In the later stages of a bronchitis, if the cough is still rather unproductive, potassium iodide (0.2 Gm every two to four hours) is more efficient than are the others It is liable to be too irritative and to aggravate conditions in an acute bronchitis Any one of the salines may well be prescribed in syrup of glycyrrhiza the flavor of which is much improved—rendered actually delicious—by the addition of 25 per cent of elixir of anise. For variety, one may use any one of a number of other flavoring syrups, such as raspberry, orange, wild cherry, tolu or tar, so that patients may not get the idea that they all and always get the same medicine because it tastes the same. Steam inhalation, with or without tincture of benzoin addition as flavor, is the second most important loosening influence The nauseants, such as ipecac, apomorphine or antimony and potassium tartrate, are too well established clinically in acute bronchitis to be disregarded because of inability of pharmacologists to offer a satisfactory explana-

tion of their mode of action and they may be added to the salines with the hope of still further directing the excretion of the water

Once the cough is loose and expectoration free, all of these agents are useless. It is at this time that improving nutrition by determining more blood to the affected surface is of value, as is done by tar in the treatment of skin disease. Indeed, as good a remedy as any for this purpose is creosote the beech-wood tar derivative. This may be inhaled its inhalation possibly being rendered more pleasant by the addition of an equal amount of alcohol and of chloroform. Or else it may be given internally in the form of creosote carbonate, in ascending drop dosage shaken up and emulsified with milk three times daily after meals. Terebene or terpin hydrate acts similarly and any of them are probably useless in the small dosages in which they are generally prescribed.

To improve resistance heat is the paramount agent in acute infection the warmth of bed hot drinks heating applications to the chest steam inhalation. In subacute and chronic conditions improvement of the general nutrition is the great desideratum and in addition to liberal feeding (possibly including cod liver oil) sunshine and fresh air are the great reconstructive tonics.

EXCESSIVE USE OF BROMO SALTZER

To the Editor—H. W. a man aged 36 was seen by me for the first time Dec 6 1932 when he complained of a tremendous frontal headache following an accident two days previously when he had been struck down by an automobile. The right orbit was contused there had been some bleeding from the nose and mouth at the time of the accident. The pulse was 112 and the blood pressure 178 systolic 110 diastolic. There were no ocular signs evident spasticity or increased patellar reflexes and the Babinski reflex was negative. Nevertheless I felt that a roentgenogram of the skull should be made which was negative for fracture. Since that time I have learned that he has suffered almost constantly with headache for the past four years although never of such severity as at present. He tells me that he has had the sinus punched out once with some relief. The teeth were roentgenographed at Walter Reed Hospital and doubtful ones removed. The kidneys are negative to urinalysis. The Wassermann reaction has not been reported as yet. I cannot find further evidence of chronic infection. The blood pressure remains elevated and the headache if anything is becoming progressively more severe and resistant to narcotics. I have recently become suspicious that he uses too much Bromo-Saltzer for his own good. However the pain was evidently the cause for forming the habit and I am not certain how much bearing this fact has on his condition. The preparation contains 20 grains of acetanilid to the ounce and I presume could raise the pressure transiently when taken in such huge amounts as the druggist tells me he purchases and has purchased over the past four years. Are there further means of looking for chronic infection or intracranial pressure as a possible cause from some other source?

M. F. RAINE MD Fayetteville W. Va.

ANSWER—From the history it seems probable that the accident plays no part in the clinical picture other than as a cause of exaggeration of the headache. As suggested also the headache seems to have preceded the abuse of Bromo-Saltzer. Some of the consequences that may follow the excessive use of this drug were given in an article dealing with bromism in mental cases (Wagner C. P. and Bunbury D. Elizabeth. Incidence of Bromide Intoxication Among Psychotic Patients. THE JOURNAL Dec 6 1930 p 1725). The duration of the illness the rapid pulse rate and the absence of neurologic signs render it improbable that the condition is due to increased intracranial pressure from an expanding lesion. It seems most probable that this is a case of essential hypertension in which headache is frequent. It is important to exclude syphilis and to look for nitrogen retention in the blood. If these are excluded therapy must be directed toward relief of the hypertension through a regimen of rest and proper diet, with administration of appropriate drugs as indicated.

POLLEN INCIDENCE IN MICHIGAN

To the Editor—I would much appreciate receiving from you an expression of opinion regarding the advisability of sending to Charlevoix, Mich. a patient suffering from hay fever. Have you for sale or distribution a chart showing the pollen free districts in the United States?

DAVID PAUL WALDMAN MD New York

ANSWER—If the patient is sensitive to the pollen of trees or grasses there would be no advantage in sending him to Charlevoix, Mich. If he is sensitive to pollen of ragweed and if he now lives in central or southern Michigan or elsewhere in the Central states, it is likely that he would receive some benefit by the change. Much would depend on the degree of his sensitivity. The pollen content of the air at Charlevoix is probably not less than at Mackinac where the total amount of ragweed pollen found in the air during the season is about one tenth as much as at Detroit, Chicago or Cleveland. The

cities along the east shore of Lake Michigan enjoy comparative freedom from ragweed pollen when the wind blows from the lake, but when the wind blows from the land concentration, are often sufficient to cause considerable suffering.

There are no pollen-free localities in the United States. There are districts that are free from certain kinds of pollen. The only area in the United States which is entirely free from ragweed pollen is the north Pacific Coast. California and Arizona are also comparatively free. There are also such local resorts as the White Mountains of New Hampshire which are reported to be ragweed free. We have no definite figures on these resorts. A table containing the annual ragweed pollen figures for a number of cities in the United States over a period of four years appeared in an article by O. C. Durham (The Ragweed Season of 1932 J. Allergy 4 105 [Jan.] 1933).

INULIN IN DIABETES

To the Editor—In THE JOURNAL, February 4 there appeared an editorial in which it was implied that inulin is an available source of energy and is utilized as are other carbohydrates. It has been our understanding that inulin is not utilized because the animal body does not secrete an inulase for its hydrolysis. This is expressed in a discussion in Hawk Bergheim's Practical Physiological Chemistry (edition 9 p. 95). What is the latest authentic information on this question? We are preparing for publication a handbook of dietetics and should like this information to include with reference to foods containing inulin (mushrooms salsify dandelion soy bean and artichokes).

ESTELLE E. HAWLEY
ESTHER E. MAURER
Department of Vital Economics
University of Rochester Medical School Rochester N. Y.

ANSWER—Inulin is a polysaccharide carbohydrate that yields the simple sugar fructose (levulose) on hydrolysis. It is thus analogous to the more familiar polysaccharides starch and glycogen (formerly designated as animal starch), each of which yields, on hydrolysis, the simple sugar dextrose. The editorial referred to was incorrect in its implication that inulin itself ($C_6H_{10}O_5$) is a sugar. Inulin differs from starch glycogen and dextrins derived from either of the latter in that the animal body produces enzymes—amylases—that readily convert these dextran carbohydrates into sugar whereas so far as is known there is no inulase that effects a comparable digestion of the levulin inulin. It has repeatedly been demonstrated that amylolytic saliva pancreatic juice or intestinal juice fails to act on inulin. The latter is however slowly hydrolyzed by acid of the strength of that of the gastric juice at body temperatures. So far as is at present known, inulin cannot be utilized as such by the body. The only physiologic opportunity for utilization lies in the possibility of intragastric hydrolysis to fructose (levulose). The extent to which this actually occurs during alimentation depends on the length of the period during which inulin or inulin-yielding products may remain in the stomach, the effective acidity attained in the gastric contents at the time and the diminution of gastric acidity by other substances such as proteins that accompany the meal. Feeding tests have shown that inulin does not effectively lead to glycogen formation whereas levulose derived from inulin by hydrolysis readily does. This is further evidence that inulin per se is not readily used as the familiar dietary carbohydrates are though the possibility of some utilization cannot be refuted, for reasons already pointed out. Earlier feeding experiments on diabetic patients led to the assumption that inulin is an advantageous food for them. Presumably what happened was that the inulin was destroyed by microbiotic agents in the bowel or excreted in the feces. Under such circumstances the lowered urinary sugar in the diabetic patient would be attributable to lack of absorption rather than to superior utilization. The literature of the subject is reviewed by Joslin E. P. Treatment of Diabetes Mellitus ed 4 Philadelphia Lea & Febiger, 1929, page 629. On the basis of empirical experience he is inclined to believe that inulin in the form of Jerusalem artichokes may be used in small amounts for intermittent periods with pleasure and profit. This is the most favorable opinion that we have found. It is important to point out that inulin occurs primarily in the Compositae. It is present in the Jerusalem artichoke—the Topinambour of Europe—which should not be confused with the entirely different species commonly sold in this country as 'French artichokes'. The soy bean ought not to be included in the list of inulin-containing food. Many efforts have been made to grow and market Jerusalem artichokes on a large scale in this country but without much commercial success. Persons should be warned that ingestion of large quantities of inulin is not infrequently attended with alimentary distress presumably due to fermentation.

KIUMA

To the Editor—What is Kiuma which has been the subject of a blatant advertisement from the president's office of E. Fougera and Co?
B C D Danbury Conn

ANSWER—According to the advertising the preparation is derived from a "sort of ooze from a native tree from Africa a foul smelling thick gummy substance." Chemists were engaged to overcome the peculiar odor of this gummy material and in so doing they isolated what is stated to be a salicylic ester of dihydroxethane having a salicylic acid content of approximately 90 per cent

A letter was sent to E. Fougera & Co., Inc. by the A M A Chemical Laboratory inquiring whether or not the product was secret and if not what was the quantitative statement of composition. In reply the president of the firm stated that the principal ingredients are the base which is brought from Central Africa, and S E D a new salicylic ester discovered by a British chemist while endeavoring to mask the odor of the basic substance brought from Africa. Particularly amusing was the statement in the letter

Kiuma is being advertised to the medical profession only and in such a way as to place the decision of its efficacy in the hands of the doctor himself in his practice

Evidently E. Fougera & Co. does not appreciate that in the exploitation of drugs to physicians the burden of proof should lie on the manufacturer. It does not reflect credit on the firm nor aid public health when a firm suggests that physicians use a product secret in composition as an experiment for the manufacturer in determining whether or not the substance is of value. As has been pointed out so frequently a physician owes it to himself, to the patient and to the public welfare not to use a compound the composition of which is secret.

There is no evidence available to show that this preparation has been tried in comparison with other well known ointments such as salicylic ointment or "Whitfield's ointment."

Of course the product does not stand accepted for inclusion in New and Nonofficial Remedies, nor has it been submitted to the Council for consideration.

IMMUNIZATION AGAINST TYPHOID

To the Editor—Please give me the latest accepted opinion on the following points: 1 If an adult person is given the typhoid immunization every three years how many years will be required to confer permanent immunization? 2 Does an attack of typhoid confer any degree of immunity? 3 Does an attack of typhoid predispose to subsequent attacks? 4 At what age if any is a person considered practically immune to typhoid?
C A MICHAEL M.D. Austinville Va.

ANSWER.—1 This question cannot be answered satisfactorily because no knowledge exists bearing directly on the main point. All that may be said with assurance is that with each successive immunization and with the passage of years the immunity undoubtedly would increase.

2 and 3 An attack of typhoid leaves behind it protection against future infections with typhoid bacilli and does not favor subsequent infections.

4 Typhoid is a disease especially of youth and early life. After 40 the disease gradually falls off but it may occur even in old age though rarely. Practically it may be said that after 50 immunity seems to be well established.

EFFECTS OF CHLOROPHYLL ON BODY

To the Editor—What is the latest theory regarding chlorophyll in vegetable matter in relation to its ingestion in the human body? Has it any effect on man either as a food or as a chemical?

C M PETERS M.D. Canton Ohio

ANSWER.—The researches of recent years have indicated an interesting chemical relationship between the plant pigment chlorophyll and the animal respiratory pigment hemoglobin. This has sufficed to raise the question whether in the animal organism hemoglobin is actually derived from the widely found chlorophyll of plants. It is conceivable on this basis that somehow chlorophyll is converted directly or indirectly into the blood pigment in herbivorous species from these the carnivora might eventually secure their hemoglobin. As a matter of fact however it is experimentally demonstrable that the embryonic organism can produce hemoglobin without having received either hemoglobin or chlorophyll in its pabulum; furthermore, herbivora also can thrive on a ration devoid of chlorophyll. The only established connection between the two pigments lies in the circumstance that they are built up chemically out of the same cyclic components of the protein molecule. A pyrrole group seems to be involved in each

case. In their disintegration, hemoglobin and chlorophyll lead to similar if not identical end products. On the basis of such information and indirect inferences it has been assumed that the human organism can transform the green leaf pigment into the red blood pigment. A combination of chlorophyll (which is iron free) and iron has been recommended, notably by the Swiss investigator Bünig, as a product capable of hematopoietic possibilities. This applies to increase in number of red cells and also in content of hemoglobin in the blood of man. The claims have not won widespread acceptance.

TUBERCULOSIS ANTIGEN MORRISON

To the Editor—I am in receipt of three 20 cc. bottles of Tuberculosis Antigen (Morrison) put out by the Abbott Laboratories of North Chicago which were apparently sent by a Mr. O C Morrison of Carroll Iowa to a resident of Saskatchewan. Can you give me any information respecting this so-called chemical antigen? The T B Antigen contains the fat splitting enzymes incident to the tubercle bacillus! The type-written statement accompanying these bottles over Morrison's name seems very peculiar and there is no reference to authority or to the literature.

ALLAN C RANKIN M.D. Edmonton Alta

ANSWER.—Morrison's "Tuberculosis Antigen" seems to be a physiologic sodium chloride solution extract of tubercle bacilli dried at from 60 to 65 C., ground in a ball mill, filtered through a Berkefeld filter, and tested for sterility. It should possess the same properties of other bacillary extracts similarly prepared many of which have run the gamut of therapeutic experimentation within the last forty years. It appears to resemble the Von Ruck vaccine which has not been used since 1912 and which few people found useful aside from the originator.

RABIES IN CATTLE

To the Editor—I have a patient whose cow was bitten on the nose by a mad dog April 24. The patient used the cow's milk until April 26. He comes to me with the following questions: Is there any danger of the family developing rabies from using the cow's milk? Is there any danger of his developing rabies from milking the cow? What should he do with the cow? Kindly advise me in regard to these questions.

D D MOSHER M.D. Seminola Okla

ANSWER.—The incubation period in bovine rabies averages from four to eight weeks—rarely it may extend to several months—and consequently it seems safe to conclude that no danger has been incurred in using the milk of the cow in question or in milking the cow. As it is impossible to predict whether the cow will develop rabies no definite advice can be given with respect to the disposal of the animal. Human rabies has followed the bite by supposedly rabid cattle. If the animal is kept alive special precautions should be taken against contamination of scratches or wounds with the cow's saliva particularly as the beginning of the possible period of incubation approaches.

PROJECTING HAIRS IN NOSE

To the Editor—I have been annoyed by the small cilia or hairs projecting from the nares. I have tried plucking them out but they return with great rapidity. Can you suggest any method of removal? Please omit name.

M D Indiana

ANSWER.—The hairs, or vibrissae projecting from the nostrils have the function of keeping dust and other extraneous substances from the nose. If they are completely removed crusts form and a dermatitis supervenes. The only reason for removing the vibrissae would be that they are long and unsightly. In this event they may be carefully trimmed with scissors. They should never be plucked, as this procedure occasionally leads to furunculosis, and infections of this character about the nose have been known to produce serious complications.

CALORIC VALUE OF BEER

To the Editor—Will you kindly give me the approximate caloric value of the proteins, carbohydrates and fats contained in one pint of 3.2 per cent beer collectively exclusive of the alcohol. Please give the caloric value of the alcohol separately.

M D Washington

ANSWER.—Beer differs considerably in composition. The following figures are representative for seven types of beers, the averages of about 600 analyses being used.

Lusk in his book "Science of Nutrition," states that a liter of German beer contains from 3 to 4 per cent alcohol yielding 450 calories to the body, of which one half approximately are derived from alcohol and the rest from protein-like extractives and from dextrin.

Beer may be expected to contain in addition to its alcohol content, from 5 to 7 per cent of solid matter or extract, from

0.5 to 0.7 per cent of nitrogenous substances some of which are protein from 1 to 2.5 per cent of sugar as maltose, from 2 to 4 per cent of gums and dextrins from 0.16 to 0.4 per cent of acid as lactic acid and from 0.15 to 0.36 per cent of ash. Fat as such may be considered absent.

A pint of beer will provide approximately 250 calories. These calories are derived from the chief ingredients as follows: protein or organic nitrogen compounds 12 calories, carbohydrates 70, organic acids, 6, and alcohol, 108.

POLLENS IN CHICAGO AREA—HAY FEVER AND TUBERCULOSIS

To the Editor—I have a patient with bilateral pulmonary tuberculosis. The patient is highly sensitive to the giant and dwarf ragweed pollens. I kindly inform me of a region close to Chicago where these pollens are not present. 2. What effect does hay fever have on active pulmonary tuberculosis? Please omit name.
M D, Illinois

ANSWER—1. There is no region near Chicago where giant and short ragweed are absent over a sufficient area to render the locality free from ragweed pollen. Quantitative investigations of the pollen content of the air indicate that so-called hay fever resorts in the Great Lakes area are all subject to frequent pollen contamination from upper air currents, especially

Quantities of Ragweed in Chicago and Other Places

City	Average Daily Pollen Count*	Maximum Pollen Con- centration for 24 Hours	Dates	Average Annual Pollen Fall†
Chicago	130	502	Aug 27 1932	4 564
Mackinac	10	89	Sept 2, 1929	3.5
Sault Ste Marie	14	92	Sept 2, 1929	500
Port Arthur	0	134	Aug 30 1932	302
Winnipeg Manit	10	70	Aug 20 1931	330

* Number of granules per cubic yard of air

† Total number of ragweed pollen granules counted on daily slides throughout the season

with strong southwest winds. Statistics for ragweed from the four nearest points investigated compared with Chicago, are shown in the accompanying table. It is likely that by going into the wooded regions of central Ontario the ragweeds could be entirely escaped. In the United States only western Washington and western Oregon are absolutely free from ragweed pollen (Durham O. C. The Ragweed Season of 1932 in the United States, Canada and Mexico, *J Allergy* 4 105 [Jan] 1933).

2. Hay fever occurs in association with tuberculosis in about 0.1 per cent of cases. Moderate or severe pollinosis indirectly affects the tuberculosis in an adverse direction by causing additional coughing, sneezing, loss of appetite, disturbed rest and loss of sleep. Loss of weight during the season usually results, but not rise in the temperature. Complications such as sinus infections may make matters worse, and coughing and sneezing may bring on hemoptysis.

Treatment of the pollinosis with pollen extracts should be undertaken in the usual manner with special care to avoid constitutional reactions. The treatment is just as successful in tuberculous as in other patients and should result in freedom for pollen asthma and marked diminution in nose and eye symptoms (Lichtenstein, M. R. The Treatment of Pollinosis in Tuberculosis Patients, *Am Rev Tuberc* 26 235 [Sept] 1932).

DETERMINATION OF RIGHT OR LEFT IN X-RAY FILM

To the Editor—An x-ray film of a knee is presented not labeled. Can you tell me in what manner I may determine whether one is dealing with the right or left knee? Please omit name.
M D, New Jersey

ANSWER—If the film is a duplitzed one (i. e. with emulsion on both sides) it will be impossible to determine from the film alone which knee one deals with unless an opaque marker of some kind was placed on the film during the exposure, or unless the technician picked up the film in such a way as to note right or left side and placed a pencil notation on the film in the dark room.

PSYLLIUM SEED FOR DIABETES

To the Editor—Has psyllium seed any carbohydrate value? Is it to be considered in the handling of diabetic dietetics?
M D, New York

ANSWER—No. The seed passes through the alimentary tract without being digested. It can be used by diabetic patients.

Minnesota January Report

Dr. E. J. Engberg, secretary, Minnesota State Board of Medical Examiners, reports the oral, written and practical examination held in Minneapolis, Jan. 17-19, 1933. The examination covered 12 subjects and included 60 written questions. An average of 75 per cent was required to pass. Eighteen candidates were examined all of whom passed. One physician was licensed by reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent
University of Minnesota Medical School (1932)	85.5	86.1	86.2
Washington University School of Medicine (1932)	85.1	86.2	87.3

Book Notices

Final Report of the Commission on Medical Education. Cloth. Pp 560
New York: Commission on Medical Education, Office of the Director of
Study 1932

In the period of readjustment following the societal upheaval caused by the war, it was natural that questions should be raised concerning the place of medical training in the general scheme of education and the fitness of our medical schools to discharge satisfactorily their obligations to the social order. On the one hand, higher entrance requirements adopted in 1918, together with the demand of military service, had materially reduced the number of medical students. On the other, many of the physicians returning to civil life did not return to their former locations but sought to establish themselves in larger centers of population which offered greater social and financial opportunities. Altogether, the situation demanded a searching analysis of the social aspects of medical practice and of those institutions which were attempting to prepare the members of the medical profession for the service which they would be called on to perform. At the instigation of the Association of American Medical Colleges, a commission was appointed to undertake this inquiry. After seven years it has presented in this final report the results of its investigations and observations. In its findings the commission lays no claim to originality but endeavors merely to reflect and emphasize the soundest current opinion on a few of the salient principles of education.

The report deals, first of all, with the social aspects of medicine, discussing such topics as specialization, physicians' incomes, the economics of medical care, sickness insurance, industrial medicine, group practice, and hospitals. An attempt is made to appraise the need for medical service by statistics gathered from various sources showing what is actually being done for people in selected groups. Information collected regarding the supply and distribution of physicians leads to the conclusion that the United States is oversupplied to the extent of about 25,000, and that at the present rate of production, the ratio of physicians to population is still increasing.

Emphasis is laid on the necessity for advanced training through internships and postgraduate courses. Every physician must continue to be a student throughout his professional life. Both the universities and the medical profession share the responsibility for providing opportunities for the further instruction of medical graduates. Specialism is an essential part of modern practice, but the public and the profession have suffered by reason of those self-constituted specialists who lack adequate training in their respective fields. A particular identification should be established for qualified specialists obtainable only on evidence of the successful completion of a suitable course of training and on demonstration of the requisite skill. Briefer courses are also needed to enable the practitioners in smaller communities to keep in touch with the rapid advance of medical

science. The internship is coming to be generally regarded as an important stage in the preparation of the physician for his work. That this conception may be justified, it is necessary that hospital services be organized with educational objectives clearly in view.

The purpose of professional licensure, in theory at least, is to protect the public. In practice however, according to Dr Rappleye, this aim has been largely frustrated by what amounts to multiple standards of practice due to legislative recognition of the cults. The several expedients and political compromises that give legal and public recognition to sects and branches of medicine based on different educational standards are not in the interest of sound public policy. All practitioners of the healing art should be thoroughly trained, and every effort should be made to create a public opinion that will support a program of medical licensure based on a single and adequate educational requirement. The function of testing the fitness of the candidate now exercised by the state boards should in the view of the commission be transferred to the university, and a license to practice granted directly on the basis of graduation from an approved medical school.

Although the objective of medical education is a sound preparation for some form of medical practice, the standard four year course of this country cannot produce a physician. At best it can provide an opportunity for the student to obtain an elementary knowledge of the medical sciences and their application, a training in the methods and spirit of scientific inquiry, and such information as comes from association with men who exemplify the highest ideals of the profession. It is on the character of the student, his intelligence, industry and ability, that results largely depend. The aim should be, therefore, to develop in him sound habits of study and arouse an interest in the fundamental problems of medicine which will stimulate him to continue his own self-education throughout his professional career. To this end, greater responsibility is placed on the student for his own training.

The report shows that efforts are being made to correct the teaching of too many subjects in too great detail, the dependence on memory alone, the artificial separation between the medical sciences and clinical teaching, the overemphasis of specialties, and the inadequate instruction in therapeutics and preventive medicine. Greater stress is being laid on the early diagnosis and appropriate treatment of disease of insidious onset. Mental hygiene is assuming an importance commensurate with its social, medical, legal and economic implications.

In his conclusion Dr Rappleye says "The hope of democracy is in trained leadership. The medical profession is the trustee of the essential knowledge and has the personnel necessary to solve a large national problem. It will occupy its proper place in society to the extent that it provides leadership and an effective program of medical service built upon thoughtfully conceived plans of medical and postgraduate education, proper organization of the profession, and the advocacy of unselfish and courageous public and professional policies."

"Sickness affects, sooner or later, every member of society. Provision must be made to care for it, with full recognition of the technical character of the services involved, of the necessity for public education regarding the value and limitations of scientific medicine, and of the importance of creating conditions which will attract and retain the highest type of physician, dentist, nurse, and public health administrator. There is urgent need for the coordination of the efforts of the various groups and individuals in the field to the end that all may actively participate in achieving the aims of a collective policy."

The commission has made a valuable contribution in the wealth of material which it has presented in this report and also in analyzing the many factors economic and social, now influencing medical practice. It has clearly portrayed the present trends in medical education, which is conceived as a single process beginning at the time of entering college and continuing to the grave. There will be dissent from some of the recommendations in the report, as, for example, the elimination of the state examination for licensure. But, as a whole, it cannot be too highly commended for its clear cut demonstration that what the country needs is better not cheaper medical service that the cost of such service is not excessive, though at times it may be inequitably distributed, and, of paramount importance, that the cornerstone of the entire structure of

public and private health is the individual physician, without whose personal qualifications of character intelligence, judgment and skill no scheme of medical practice, however organized, can succeed

Medizinische Kolloidlehre Herausgegeben von Prof. Dr. L. Lichtwitz Direktor der I. Inn. Abt. des Rudolf Virchow Krankenhauses Berlin Dr. Dr. Raphael Ed. Liesegang und Prof. Dr. Karl Spiro Direktor des Physiologisch Chemischen Instituts der Universität Basel Lieferung 1. Allgemeine Kolloidlehre in Beziehung zur Biologie und Pathologie. Paper Price 5 marks. Pp. 80 with 10 illustrations. Dresden & Leipzig: Theodor Steinkopff 1932

An Expert-Conducted Tour for Medical Men Through the Wonderland of Colloid Chemistry' would probably be an appropriate title for this work if the other instalments live up to the promise of this one. Not that this is mental pabulum for the uninitiated. It is on the other hand, not written as exclusively for the expert as so many other books on 'colloids' are which contain such a morass of mathematics that any non-expert gets mired in it. Liesegang's introduction alone is worth the price of admission. Protoplasm is pictured as a felt-work of fine fiber-shaped colloid particles intermingled with an emulsion, kept by antagonistic influences (K vs Ca, lecithin vs cholesterol and so on) at a critical point at which change to water-in-oil or oil-in-water emulsion readily occurs. Changes in either direction as by excess of K over Ca, or vice versa, even when exerted only at the surface of the cell may give a mental picture of the nature of certain drug effects, e. g. vagotonic and sympathotonic action. Paul Meyer's chapter on colloid osmotic pressure and Ferdinand Herçik's on 'surface tension' are included in this instalment. The importance of the publication of this work lies in the growing conviction of the fruitful influence of the colloid-chemical viewpoint upon biological physiologic and purely medical questions. Indeed the assertion has been made that real progress in the domains of pathology and therapy is chiefly to be hoped for through the physicochemical and colloid chemical point of view.

Guide to Radiologic Diagnosis in Heart Disease Prepared with the Aid of the Committee on Research of the Heart Committee. By Geza Nemet, M.D. Paper Price 35 cents. Pp. 33 with 31 illustrations. New York City: New York Tuberculosis and Health Association Inc. 1931

Criteria for the Interpretation of Electrocardiograms Prepared with the Aid of the Committee on Research of the Heart Committee. By Arthur C. DeGraft, M.D. Paper Price 35 cents. Pp. 19 with 37 illustrations. New York City: New York Tuberculosis and Health Association Inc. 1931

These two pamphlets were apparently sponsored by the Heart Committee to aid in clearing up confusion in terms and techniques. The first suggests methods by which the radiologist and the clinician may meet on common ground and includes valuable diagrams to accomplish this purpose. The second attempts the same meeting place for the electrocardiographer and the clinician. Fifty key numbers are given which represent the electrocardiographic curves that are most commonly encountered. Each curve is illustrated by an example. The idea actuating both pamphlets is to extend uniformity in cardiac diagnosis.

The Principles and Practice of Obstetrics By Joseph B. DeLee, A.M., M.D. Professor of Obstetrics and Gynecology at the University of Chicago. Sixth edition. Cloth. Price \$12. Pp. 1163 with 1221 illustrations. Philadelphia & London: W. B. Saunders Company 1933

In offering this new edition of his monumental work, Dr. DeLee expresses his conviction that the general surgeon, the occasional accoucheur and the family practitioner who has to do his work in the home or in a small understaffed maternity ward of a general hospital may well be replaced by a well trained midwife. Since the vast majority of births still occur in the home, the advice given in this volume is in the main conservative. The text has been revised, new illustrations have been added, and there are references to the new literature of endocrinology and anesthesia and pregnancy tests. Consideration is taken of the great advances in the field of internal medicine. Those sections of the book in which the technique of obstetrics is concerned have also been brought up to date. The position of this volume in the field it covers is so completely established that it requires no new encomium. It remains merely to say that its author has given the best that is in him to keep his book in the high place it has for so long occupied.

Contributions to the Medical Sciences in Honor of Dr. Emanuel Libman by His Pupils, Friends and Colleagues In three volumes. Cloth. Price \$15 per set. Pp. 1292 with illustrations. New York: International Press 1932.

The influence of Dr. Libman on medical men has extended into many places. His students, colleagues and associates, as represented by the contributors to these volumes, constitute a notable list. Their names and their articles reflect impressively his many interests. As is pointed out by Dr. William H. Welch in the preface, approximately one third of the papers relate to the cardiovascular system, but the others concern medical historical subjects: bacteriology, pathology and indeed the whole realm of science and the practice of medicine. It would be invidious to list particularly any of the notable names appearing in this work. Of special interest are such articles as that by Harlow Brooks on the heart of the athlete, that by Leroy Crummer on the early development of medical literature, that by Lawrason Brown on the significance of Koch to tuberculosis. Again there is a historical article by Fielding Garrison, an item by Arthur F. Hurst, entitled "On Being Liverish," and a brief paper by the famous historian Sudhoff.

Memorial volumes of this character represent a fine testimony to the person for whom they are developed, provided always, of course that the writers take seriously the assignment and prepare specifically for the purpose contributions that are not duplicated in general medical literature elsewhere. The Libman collection is notably free from the latter type and, therefore, merits a place in any library.

Leçons cliniques sur le diabète Par Marcel Labbé, professeur de clinique médicale à la Faculté de médecine de Paris. Paper. Price 40 francs. Pp. 333 with 36 illustrations. Paris: Masson & Cie 1932.

This volume represents the observations and views on diabetes mellitus of one of the foremost authorities of France. The range of subject matter covers diagnosis, complications, treatment and social aspects and although the point of view is primarily clinical and practical, the theoretical aspects are briefly but adequately indicated. The style is clear and direct and the author evidences a wide knowledge of the international literature. In general the author's views on treatment are conservatively progressive and compare quite closely with those of Joslin in this country. No extreme dietary combinations of any sort are recommended, but rather the avoidance of excessive caloric intake with a moderate carbohydrate allowance. Temporary green vegetable diets are recommended as useful. This publication serves to illustrate the parallelism between the medical thought in different countries brought about by the present international distribution of medical literature.

The Technique of Contraception: An Outline By Eric M. Vaisner, M.D. Foreword by Robert L. Dickinson, M.D. Introduction by Foster Kennedy, M.D. Published for the American Birth Control League Inc. Paper. Price 50 cents. Pp. 38 with 32 illustrations. Baltimore: Williams & Wilkins Company 1933

This outline is published by the American Birth Control League. It concludes that the sheath in general shows a high degree of success and that any method involving the use of intra-uterine stems is to be avoided because of a high rate of dangerous sequelae. It points out that the method most commonly advocated involves the use of some form of mechanical barrier in conjunction with a spermicidal jelly. It is realized that the ideal contraceptive has not yet been found.

The Practitioners Library of Medicine and Surgery [Supervising editor: George Blumer.] Volume III: Practice of Medicine. Associate editor: Harold M. Warren, B.A., M.D. Assistant Clinical Professor of Medicine, Yale University School of Medicine. Cloth. Price \$10. Pp. 1-60 with 44 illustrations. New York & London: D. Appleton & Company 1933

The first two volumes of this series have previously been reviewed in THE JOURNAL. The third volume is devoted to the infectious diseases: those due to parasites, to physical agents and toxic agents, to allergy and metabolism, to the diseases of digestion and respiration of the heart and the blood-forming organs and finally to the endocrine glands and the locomotor system. It is thus in its way almost a complete textbook of medicine, a volume of immense value to any practitioner. This is particularly the case since the various sections have been written by competent authorities with practical experience in

the subjects about which they write. The editorship has apparently included an order of discussion approximating the outline established by Osler. Such an outline makes reference exceedingly simple. It is not possible in the scope of this review to criticize particularly any one article. In general the articles have an evenness of development and preparation that speaks well for the planning of the book. A typographic error occurs in the heading "Acquired Aliments of the Feet," on page 1323.

Lincoln A Psycho Biography By L. Pierce Clark. Cloth. Price \$3.50. Pp. 570 with 9 illustrations. New York & London: Charles Scribner's Sons, 1933.

Dr. Clark presents many new side lights on the character of Lincoln. He applies the technic of modern psychoanalysis to the study of the available records. The book is well written and the use of the present tense gives it a vivacity not usually associated with historical accounts. As to the applicability of the psychoanalytic method, there may be some doubt. Whether or not one agrees with all of the author's conclusions, he has studied the evidence and he supports them by such observations. He believes that the life of Lincoln is not one of cold intellectual performance but rather one swayed by emotions and governed by a marvelous mind.

The Practice of Birth Control. An Analysis of the Birth Control Experiences of Nine Hundred Women By Enid Charles M.A. Ph.D. Department of Social Biology University of London. Cloth. Price 10s. 6d. Pp. 190. London: Williams & Norgate Ltd, 1932.

This is the record of birth control experiences of nine hundred women who tried many different methods, most of which are widely known to the medical profession throughout the world. There is a chapter on the comparison of results with those of other investigators and a chapter devoted to general conclusions. This indicates that the use of a sheath with a chemical or of a pessary with syringing is more reliable than any method or combination of methods commonly used. It is recognized that all contraceptive devices require a modicum of intelligence and initiative in use. Probably the most moron proof is the soluble chemical pessary, but the types now available are costly and are not altogether reliable. It is conceived by the investigators that there are factors at present operating to produce a falling birth rate and if allowed to continue some collective control will be necessary for the avoidance of the extinction of the human race. Obviously that time is far distant, since the biologic laws still continue to operate in the same old way in the vast majority of places throughout the world.

A Guide to Birth Control Literature. A Selected Bibliography on the Technique of Contraception and on the Social Aspects of Birth Control By Norman E. Himes. Cloth. Price 3s. 6d. Pp. 46. London: Noel Douglas, 1931.

This is a selective bibliography on the technic of contraception. The periodical literature to which reference is made is not easily available, so that the book is hardly worthy of purchase by the average American physician.

Endocrine Medicine By William Engelbech M.D. F.A.C.P. B.S. Volume I. General Considerations. Volume II. The Infantile Endocrinopathies. The Juvenile Endocrinopathies. Volume III. The Adolescent Endocrinopathies. The Adult Endocrinopathies. Volume IV. Bibliography. Index of Names. Index of Subjects. With a foreword by Lewellys F. Barker. Cloth. Price \$3.50 per set of 4 volumes. Pp. 460 with 138 illustrations. 473 with 214 illustrations. 862 with 366 illustrations. 117 Springfield Ill. Charles C. Thomas, 1932.

This is a system in four volumes covering all phases of endocrinology except diseases of the pancreas. The subject matter is based on a personal experience with 2,000 clinical cases.

The first volume gives a short history of the development of knowledge concerning the ductless glands, describes their organology and physiology and discusses the factors of heredity, the diagnostic procedures, the endocrine reactions including basal metabolism, specific reactions and blood chemistry and the relation of the endocrinopathies to general medicine. Each volume has a special chapter on the relation of diseases of the ductless glands to public health. This phase of the work is interesting and can be studied by any one with profit. Volume

II describes the infantile and juvenile and volume III the adolescent and adult endocrinopathies. The same plan is followed in these volumes, necessitating much repetition. The work represents an enormous acquaintance with the literature and an extensive experience and can therefore be resorted to for reference purposes. As recent as it is, it is already deficient in certain ways, not because of the author's neglect but because of the rapid advances that have been made in endocrinology. It would seem that a loose leaf system might correct this defect. All three volumes are profusely illustrated and contain numerous charts of standard measurements. Volume IV contains the bibliography and the index.

It is unfortunate that the untimely death of the author has prevented him from reaping the benefits that would have accrued to him through the publication of such a monumental piece of work.

Beiträge zur Kenntnis der Narkolepsie Von Prof. Dr. med. et phil. Rudolf Thiele unter Mitwirkung von Priv. Doz. Dr. med. Hermann Bernhardt. Sonderausgabe von Heft 69 der Abhandlungen aus der Neurologie, Psychiatrie, Psychologie und ihren Grenzgebieten. Paper. Price 18 marks. Pp. 187 with 2 illustrations. Berlin: S. Karger, 1933.

This book is based on a thorough and detailed study of thirty-one patients suffering from narcolepsy. In eight instances encephalographic studies were made. While no attempt is made to review the literature, those articles which are pertinent to the discussion of isolated points are carefully cited. The authors are convinced that narcolepsy should be considered a syndrome and not a disease *sin generis*, as maintained by many writers, notably Adie. They are impressed with the value of treatment with ephedrine as recommended by Janota and by Doyle and Daniels. Throughout, there is manifested a critical but dispassionate point of view. It is to be regretted that a work containing so much data of value does not have an index.

Men Against Death By Paul DeKruif. Cloth. Price \$3.50. Pp. 363 with illustrations. New York: Harcourt, Brace & Company, 1932.

In this volume are collected most of the essays contributed by DeKruif to the *Country Gentleman*, the *Ladies Home Journal* and the *Forum*. The difficulty with these writings as with some previous essays is their excess in dramatization and an absolute plethora of superlatives. Those like the DeKruif of former years who work in laboratories of research and those who, unlike DeKruif, have taken care of the sick at the bedside know that superlatives are rare and in general the atmosphere is quiet. Nevertheless for the vast majority of lay readers writing that fairly burns and explodes has a great appeal. It is not surprising that the contributions of DeKruif should have done more to spread interest in the drama of medical science in its progress against disease than those of any other writer.

Les constipations. Diagnostic et traitement d'après les conceptions actuelles Par M. Chiray, médecin de l'Hôpital Bichat et R. Stieffel, médecin consultant à Plombières. Collection médecine et chirurgie pratiques no. 59. Avec une note historique de Jean Vinchon. Paper. Price 20 francs. Pp. 157. Paris: Masson & Cie, 1933.

The title of this book, "The Constipations," is to emphasize that there exists a variety of forms of constipation. An interesting chapter on the history of constipation by Jean Vinchon, is followed by a fairly thoroughgoing discussion on the physiology of the colon and the classification and diagnostic differentiation of the various forms of constipation. The authors favor the division into two great classes: functional constipation and "lesional" constipation. The diagnosis, including roentgenologic criteria, and the treatment, including surgery, are taken up from a thoroughly modern point of view.

The Long Hills By Frederic Brush. Cloth. Price \$2. Pp. 170. Philadelphia: Roland Swain Company, 1932.

The author is a physician, a woodsman and an athlete. His poems constitute a saga of the Alleghenies. In a series of poems he tells a story of the opening of the Alleghenies to new civilization, occasionally pausing for a brief chapter in prose and varying his verse form by many rhythms. Particularly interesting are occasional Americanisms typical of the language of the Alleghenies. For example, "She scrouched down," "he grows rampageous," "he's pastin' Danny," "this razoo is just begun." There is a story of an old fashioned wrestling match

in rhyme reminiscent of Masefield Among the medical contributors to poetry, Dr Brush earned a place for himself by his former book *Susquehanna* "The Long Hills shows progress in his art and technic

Medicolegal

Compensation of Physicians Liability of Minor Child—Thaddeus Goss, 6 or 7 years old was treated by the physician-plaintiff for serious injuries resulting from an automobile accident. He recovered \$3,000 damages, which after deducting expenses, was paid to his guardian, his codefendant in this case. The child's father T. R. Goss, recovered in his own name \$900 damages, which according to his complaint filed in the case, included hospital and medical expenses that he had incurred on account of the injury to his son. There was no express agreement by any one to pay for the services rendered. The father refused to pay, and the physician thereupon sued his patient, the minor child and his patient's guardian, the defendant bank. From a judgment for the physician, the defendants appealed to the Supreme Court of North Carolina.

The question presented on appeal, said the Supreme Court, is, "Is an infant living with his father liable for medical services where such services were uncontradicted [sic] but were necessary in an emergency and the infant recovers damages for the injuries which made the services necessary, although the father also recovers for his own expenses (including hospital and medical) and damages?" It goes without saying said the court that the father is liable to the physician for the services rendered his infant son. The defendants themselves had pleaded that "In good conscience and equity it [the amount due] ought to have been collected out of the father when he recovered his judgment in a substantial amount for this very obligation." With this suggestion, the court agreed but it pointed out that from the record before the court the father might be insolvent. Under the circumstances of the case, the court concluded that the minor child, too was liable. In reaching this decision the Supreme Court quoted with approval *Cole v. Wagner* (N. C.), 150 S. E. 339 as follows:

It was an emergency and quick action had to be taken. During the period of treatment the father paid for no hospital medical or surgical treatment for the infant. It seems that he was either unable—at least he did not provide for the infant. The circumstances were peculiar. The father did not provide this attention necessary to save his life and usefulness the hospital did. The infant now has an estate and it is unthinkable that the guardian of the infant should not pay the reasonable expense for saving the child's life and usefulness.

In the present case, concluded the court the physician-plaintiff rendered services in an emergency and to preserve human life and the minor child benefited thereby should be held liable to the physician for reasonable compensation for such services. The judgment in favor of the plaintiff was therefore affirmed.—*Bitting v. Goss* (N. C.) 166 S. E. 302.

Compensation of Physicians Termination of Physician's Contract, Frequency of Visits—The defendant casualty company authorized employers holding its indemnity policies to summon certain physicians named by it to treat injured employees. The physician-plaintiff whose name was on the casualty company's list, was so employed by an insured employer in this case, Dec. 22, 1926. The company was aware of his employment, for he made written reports to its officers, the last one dated March 5, 1927, and he claimed to have made later reports by telephone. About the middle of 1927, or in the fall of that year, the casualty company struck his name from its list of physicians whom its policyholders were authorized to employ. It said nothing, however, and did nothing to indicate that he was to discontinue attendance in this case. He therefore continued in attendance until the patient's death, during December, 1928. In May, 1928, he sent a bill to the casualty company, which the company seems to have ignored although there was no denial of the receipt of the bill by the company. After the patient's death, he sent another bill. When the company ignored that also, he brought suit. The company, by way of defense, contended that it had no knowledge that the plaintiff was in attendance on the case after March 5, 1927,

the date on which the plaintiff rendered his last written report. Practically all of the reports, however, closed with the words "Will keep you advised as to his [the patient's] progress."

If the defendant casualty company desired to terminate its liability after March 5, 1927, said the Kansas City court of appeals Missouri, on appeal from a judgment in favor of the plaintiff, it was the duty of the company so to notify the physician and to direct him to discontinue treatment. A person who employs a physician to attend an urgent case and makes no limitation as to time is liable to the physician for all subsequent visits, until the physician's services are dispensed with. The defendant casualty company further contended that the visits claimed to have been made by the plaintiff were excessive in number. But, said the court of appeals, although the number of visits to be made by an attending physician may be limited by direction of the patient or by the employer of the physician, in the absence of any specific understanding or direction the law recognizes that the physician is the best, if not the sole, judge of the necessary frequency of his visits, and so long as the patient is in the physician's charge it will be presumed that the visits made were necessary and proper.—*Nigro v. Maryland Casualty Co.* (Mo.) 53 S. W. (2d) 414.

Drunkenness and Contractual Capacity—A grantor has mental capacity to make a deed if he has sufficient mind and memory to comprehend the nature and effect of his act, if he is able to understand the nature and effect of the business in which he is engaged, and if he is exercising his own will. Evidence that a grantor is addicted to the use of intoxicating liquor is competent on an issue of mental capacity to make a deed. Proof that the grantor was using liquor to excess about the time the deed was made will not be sufficient to set the deed aside, however, unless it appears that he was so intoxicated as to be incapable of understanding the transaction and of exercising his will. Neither proof of old age, eccentricity, partial impairment of mental faculties, nor of loss of temper and ungovernable fits of passion is sufficient alone to show want of mental capacity to make a deed.—*Harrington v. Travis* (Ill.) 182 N. E. 769.

Dental Services as "Necessaries of Life"—Under a state statute imposing on the wife liability for "necessaries of life" furnished the husband, a wife is liable for dental services rendered her husband.—*Smith v. Buntson* (Calif.), 15 P. (2d) 910.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Pulmonary Diagnosis with Iodized Oils—Goodman believes that the use of iodized poppy-seed oil is indicated in the following instances (1) in pulmonary suppuration exclusive of tuberculosis, (2) in pleural suppuration of the chronic type especially complicated with fistula, (3) in lung abscesses as an aid in localization and in determining the extent of the associated

bronchiectasis, (4) to determine the efficiency of collapse therapy in nontuberculous suppuration, (5) in neoplasms of the lung and mediastinum, and (6) in tuberculosis, in which the indications are more sharply defined. Iodized poppy-seed oil should be used in tuberculous cases only when particular and definite information is desired and when other methods will not suffice. Its usefulness to determine the efficiency of collapse therapy in tuberculosis need only be mentioned to be appreciated. The lesion, of course, should be definitely fibrotic. The contraindications are (1) active pulmonary tuberculosis, (2) recent hemoptysis, (3) decreased vital capacity, (4) most cases of asthma, (5) cachectic and debilitated patients, and (6) age, which is not necessarily a contraindication. Bronchography is an essential feature of any pulmonary diagnosis. Its administration by puncture of the cricothyroid membrane by a specially devised cannula is both certain and dependable. The procedure is entirely safe.

Pathologic Physiology of Ileus—Stout believes that the ability of the intestinal mucosa to absorb water is impaired in ileus and that there is an increased secretion of liquids into the intestinal lumen. Ileus may be defined as a disorganization and impairment of the motor function of the gastro-intestinal tract, sometimes resulting in complete cessation of motor activity with consequent functional obstruction, with blood chemistry changes and toxemia peculiar to these. He presents the following as the fundamentals of treatment. 1 Proper preoperative preparation of the patient should be done. The use of cathartics preceding laparotomies is unnecessary and is to be deprecated. 2 The early recognition of the signs and symptoms of ileus and the immediate institution of adequate therapy is necessary. The objective and subjective symptoms of incipient ileus are nausea, vomiting and "gas pains" later than eight hours post-operatively, restlessness, gastric retention, tympanites and oliguria. 3 Patients who are apprehensive, irritable and later excitable from their toxemia should have proper sedation. Rest is imperative and may usually be provided by the use of sodium bromide as a basic sedative and the more potent barbituric acid salts as required. 4 Exhibition of chemicals known to have a specific action in inhibiting the toxic process, namely, sodium chloride and sodium bromide is required. 5 Toxic absorption from the intestine should be prevented. Provision should be made for the continuous removal of gastro-intestinal contents. 6 Adequate facilities should be provided for the control of intra-intestinal pressures. The operation of enterostomy is rarely necessary. The rectal drip does not aid in relieving distention, but it tends to maintain reverse peristalsis and its use is consequently inadvisable. 7 The physical chemistry of the body should be maintained as near normal as possible. 8 Gastro-intestinal tonicity should be improved. In this connection, solution of pituitary has been of little value. The author has used with success a hypodermic consisting of from $\frac{1}{360}$ to $\frac{1}{360}$ grain (0.0013 to 0.002 Gm) each of physostigmine salicylate, pilocarpine hydrochloride and strychnine sulphate. He has found this combination effective in stimulating the motor nerves of the intestine and as an aid in maintaining its tone. 9 Every effort should be made to improve the circulation in the splanchnic area. 10 Dehydration and its converse, hydremic plethora, should be prevented. It is well to remember when giving large quantities of liquids, that in the presence of fever there is a tendency toward retention of both water and chlorides by the tissues.

Alcohol Injection for Prolapse of Rectum—Potter and Wellman treated, over a four year period, thirteen consecutive cases of prolapse of the rectum by the submucous injection of alcohol, using the technic described by Findlay. The patients' ages varied from 1 to 13 years and the duration of the prolapse from thirteen days to four years. In most cases the prolapse involved the mucous membrane. One patient had a severe procidentia with extrusion of the sigmoid as well as exstrophy of the urinary bladder and other congenital abnormalities. The cause of the prolapse was ascertained in five of the thirteen cases, in three a marked diarrhea was responsible, in one the onset had followed typhoid and in one congenital anomalies were present. Some diarrhea had occurred in the other patients and this may have been a contributory factor in the production of the lesion. A cure was obtained in eleven patients, or 85 per cent, although several required a second injection for a satis-

factor result. One failure occurred in a child aged 7, who is now confined to an institution because of an organic brain lesion. Radical operation failed following unsuccessful injection. There was a recurrence in a child, aged 9 with a two year old prolapse only recently treated and the authors anticipate a satisfactory result with another injection. They emphasize the fact that radical operations many of them formidable procedures for use in children seem to be unjustifiable in most instances when one has at his disposal the injection method, which in the majority of cases has proved to be a safe simple and effective form of treating rectal prolapse.

*Effects of Thoracoplasty on the Heart Olga S. Hansen Minneapolis and H. W. Maly Oak Terrace Minn—p 200
*Dietary Treatment of Skin Tuberculosis S. Bommer Berlin Charité Germany—p 209

Effects of Thoracoplasty on the Heart.—Hansen and Maly state that their series of fifty-seven cases shows that the intrathoracic pathologic involvement incident to thoracoplasty almost invariably (in 87 per cent) displaces the heart more or less more frequently toward the unaffected side. The electrocardiograms also show a high incidence of postoperative changes (63 per cent). These changes were in agreement with the roentgen observations in only a third of the cases. It would seem impossible to predict the probable electrocardiographic changes from a study of the roentgenograms or, conversely, to guess the type of roentgen observations from looking at the electrocardiograms. It is probable that the electrical axis may be influenced by rotation of the heart on its longitudinal axis by fibrotic tissue affecting at times the base and at times the apex anteriorly or posteriorly, as has been shown experimentally by Meek and Wilson. It is probable that other factors such as rest in bed, toxemia and changes in weight may affect the form of the electrocardiogram since the thirty control patients who had no gross mechanical changes were also variable in their complexes. There has been no evidence of a disturbance in the conduction or of myocardial damage in the electrocardiograms. Necropsy has shown no abnormality in the weight of the heart nor more evidence of myocardial degeneration than is found in other patients dying of tuberculosis. Some of the changes in QRS amplitude probably represent changes in muscle tone associated with reduction in toxemia and increase in exercise and would appear regardless of the mechanics of collapse. The changes found in the electrocardiogram are probably due to extrinsic factors and bear no relationship to the condition of the heart muscle.

Dietary Treatment of Skin Tuberculosis.—Since 1928, Bommer has used the Herrmannsdorfer-Sauerbruch diet in the treatment of skin tuberculosis, in which common salt is entirely banished. Meat is restricted to a total weekly intake of from 500 to 600 Gm. Smoked meat sausage and boiled ham as well as smoked and pickled fish, are prohibited. The protein requirement is covered apart from milk, eggs and cheese by vegetable protein. The diet furnishes a generous amount of fat and is carbohydrate poor. Contrary to Voit's formula, which provides a daily intake of 118 Gm of protein 56 Gm of fat and 500 Gm. of carbohydrate, for a medium weight workman (67 Kg.), the tuberculosis diet allows about 90 Gm of protein 162 Gm of fat and 222 Gm of carbohydrate. From 45 to 50 calories daily are given for every kilogram of bodyweight. Therefore a patient having an average weight of about 60 Kg will receive from 2700 to 3000 calories daily. The author states that under the influence of this diet as the sole treatment tuberculous skin foci heal completely. He describes the clinical observations during all stages of the involution, particularly in lupus vulgaris. On the strength of his observations, the

chief action of the diet is regarded as an influence on the vascular system—the vascular wall cells. These have their normal function restored by the diet. All other curative processes are sequelae to the restoration of vascular function in the inflammatory region. In this process salt regulation, by salt withdrawal, and vitamin intake support each other in their action on the vascular wall cells. The addition of a physiologically equilibrated salt to the diet also gave successful results in lupus vulgaris. Its use materially simplifies the diet.

Syndrome of Pneumococcal Bronchial Obstruction Experimental Production of Atelectasis or Lobar Pneumonia with Human Pneumonic Sputum Suggestion for Preventive and Therapeutic Treatment. P. N. Coryllos and G. L. Birnbaum New York—p 290

Simmonds' Disease.—Silver calls attention to a syndrome of Simmonds' disease, rarely described and, to his belief, more common than generally accepted, that is, hypofunction of the three specific cells found in the pituitary. The disease in its fully developed form is readily recognized by the association of extreme cachexia with signs and symptoms of gonadal atrophy. The onset is often consequent on a complicated labor and among the clinical features may be mentioned premature aging early and complete amenorrhea, loss of pubic and axillary hair atrophy of the lower jaw with loss of teeth, and a profound depression of the basal metabolic rate. In addition to the advanced obvious cases, attention should be directed to the mild abortive forms that masquerade under such diagnoses as arteriosclerotic cachexia, syphilitic cachexia and latent tuberculosis. Disease in the pituitary region is of great physiologic significance and much can be learned from observing closely patients presenting signs of pituitary cachexia.

Infectious Polypoid Colitis.—Larsen reports a case of ulcerative polypoid colitis with a typical clinical history of infectious ulcerative colitis and the roentgenologic observations of polyposis with a suspected malignant condition. This type of lesion in the colon has apparently not been described before. The polyps are composed primarily of accumulations and massive clusters of large mononuclear inflammatory cells which contain the infectious agent. The etiologic agent is a gram negative bacillary organism situated for the most part within large mononuclear leukocytes. The micro-organism has not been cultivated nor were distinctive lesions induced in animals by inoculation with infected tissue.

Paradoxical Breathing.—Korol states that paradoxical breathing occurs in all air-breathing vertebrates. It depends on the narrowing or closing of the glottis during certain respiratory acts and on the unequal pressure conditions prevailing in the different portions of the respiratory tract. In amphibians and birds, paradoxical breathing, like the maintenance of residual air, serves a useful function in moistening and diluting the atmospheric air. In mammals owing to the oxygenation of the blood in all portions of their lungs paradoxical breathing impairs the respiratory function by diminishing the vital capacity and by causing breathing of stale air. With an intact thoracic wall paradoxical breathing is limited to the apical and mediastinal portions of the lungs, these regions of the chest being poorly provided with muscle. In congenital and acquired defects of the chest wall, the vicarious breathing is conspicuous in the areas of the lungs adjacent to the defects. During the activities of workers such as glass blowers singers dancers and runners, paradoxical breathing produces acute emphysema (volumen pulmonum acutum) and materially curtails the efficiency of the performers. Paradoxical breathing

is an important factor in the development of pulmonary emphysema and is largely responsible for the dyspnea and cyanosis observed in emphysema and asthma. Paradoxical breathing, by causing an interchange of material between the lungs is a common cause of interbronchial spread of infection in tuberculosis and all other diseases of the lungs

Archives of Pathology, Chicago

- *Tissue Reaction to Colloid and Lipoids from Human Thyroid Gland J A Ferguson Boston—p 244

Lipoid Histiocytosis—Robertson and Warren report a case which exemplifies the essential or primary lipoid histiocytosis wherein lipoid is deposited in an organ or localized part of the body the lymph nodes The diagnosis of lipoid histiocytosis by biopsy of a lymph node has not been reported in the literature. The diseases of Gaucher Niemann-Pick and Christian-Schüller cannot be considered here because of the absence of an enlarged spleen or liver, the fairly good general health and the negative results of roentgen examinations of the skeleton Although the lipoid elements of the blood were within normal limits in their patient as Rowland pointed out the blood serum lipoid may be either increased, normal or decreased, as the disease is probably due to a faulty storage of the lipoid.

Estimation of Phosphates in Urine—Pribram states that, in precipitating phosphate from solutions of the specific gravity of urine and varying in concentration from twentieth to two-hundredth molar by using an ammonium magnesium sulphate reagent, eight different forms of crystals are found, changing gradually according to the presence of certain amounts of phosphorus The form of these crystals can be used for an estimation of the amount of phosphorus in the urine (1) by using the predominant type of crystals and (2) by titrating the urine and using the crystal that predominates in the undiluted urine as an indicator in the highest dilution in which it appears The specific gravity of the urine and the presence of considerable amounts of urea and of sugar change the form of the crystals in a typical way For a quick estimation and in cases in which large series of urines are to be examined, the following rapid method may be used Five drops of the urine are placed on a slide (hanging drop slide preferable) with a capillary pipet 1 drop of the reagent (Dowd's reagent) is added with a pipet of the same caliber and mixed well when crystallization is complete (at least from five to ten minutes) a small drop of the mixture is placed on another slide covered with a cover glass and examined with the 4 mm objective The amount of phosphorus is estimated from the type of crystals present and with the aid of a special table made by the author

Pulmonary Varix—Klinck and Hunt describe a case of pulmonary varix in a woman, aged 46 with necropsy observations Spontaneous rupture of the varix with massive hemothorax was the cause of death There is evidence that the varix gradually increased in size and that the resulting enlargement gave rise to symptoms The rupture is believed to have occurred following progressive thinning of the wall of the varix during a prolonged period of hypertension. The authors discuss the various theories of the development of venous varices A congenital anomaly of the left pulmonary vein seems the most probable explanation of this rare condition Their case is apparently the first to be recorded in the English literature

Tissue Reaction to Colloid and Lipoids—According to Ferguson, colloid and lipid substances from human thyroids cause an inflammatory reaction in the subcutaneous tissue of guinea-pigs The reaction is characterized by the formation of foreign body giant cells, marked proliferation of fibroblasts and absence of necrosis The lesion in the tissue of the guinea-

pig is apparently caused by the lipoids of the injected material, and it is almost identical with the inflammatory structures, which may be tubercle-like in appearance, occasionally found on microscopic examination of human thyroids His experimental study appears to show that such inflammatory structures occurring at times in human thyroids are caused by fatty acids The fatty acids are formed in disintegrating follicles as a result of hydrolysis of the lipid content of the colloid and of the epithelium Such reactions are of considerable interest, because at times they have a striking resemblance to the lesion produced by the tubercle bacillus

Treatment of Pernicious Anemia by Liver Extract—McHenry and his associates found that liver extract prepared for intramuscular administration is safe, dependable and effective when used in adequate dosage. Administered intramuscularly, a given quantity of extract is much more potent (at least thirty times) than is the same amount given by mouth The intramuscular administration of the extract from 10 to 20 Gm of liver a day is fully as effective as the ingestion of the extract from 250 to 800 Gm of liver daily A good reticulocyte response has been obtained from the single injection of the extract from 50 Gm of liver Intramuscular liver therapy is of great value in the treatment of patients in severe relapse, to whom large doses can readily be given by this method with assurance of an early response The remission begins about a week sooner than when the extract is administered by mouth It is also useful in treating patients who refuse to continue to take sufficient amounts of liver or liver preparations by mouth The intramuscular administration of the extract from 100 Gm of liver a week in one or two doses is probably sufficient to maintain most patients with pernicious anemia in a good state of health It is extremely important, in treatment by oral administration of liver or liver extracts, always to give a sufficient amount, no matter how much may be required, to maintain the patient in good health with no anemia and to prevent the appearance or progression of nervous lesions

Functional Albuminuria—Jamieson and Scott point out that albuminuria is a common condition in growing young adults Its presence has been taken too often as an evidence of chronic interstitial nephritis The tests heretofore commonly used to distinguish functional from organic albuminuria have been unsatisfactory A test as described by Jehle has been carried out by the authors on a series of thirty young persons with albuminuria. They believe that this test is the most satisfactory yet devised As evidence of the importance of a mechanical factor in functional albuminuria, lordosis and varicocele were common observations Albuminuria may exist in the absence of lordosis, possibly, as Jehle has pointed out, from pressure on the inferior vena cava by a low diaphragm

Resuscitation of the New-Born—Brown divides the degrees of asphyxia in the new-born into three types 1 The depressed child who breathes occasionally in gasps, resists movements of the head and the extremities, and as a rule reacts to any form of stimulation, responds usually to the spanking-tubbing technic and promptly and vigorously to inhalations of oxygen-carbon dioxide mixtures administered by a face mask 2 The asphyxiated baby, whose respiration occurs at long intervals and only following external stimulation, whose muscles

are relaxed and who offers no resistance to the opening of the mouth should immediately be examined with a laryngoscope and the pharynx aspirated. If no reflex irritation is induced by this aspiration the glottis should be intubated under direct vision and the trachea aspirated. The reflex tone of the glottis is the best indication of the child's viability. If there is no reflex spasm of the glottis the baby is dying. Such a baby demands immediate and full oxygenation and the stimulating effects of carbon dioxide. Through a tube into the trachea, oxygen-carbon dioxide mixtures must be delivered under measured pressure. Such pressure overcomes atelectasis and allows an immediate diffusion of the oxygen-carbon dioxide mixture which relieves the right heart pressure, increases the left heart circulation and throws the necessary stimulation into the depressed respiratory center.

 Calculous Disease of Urinary Tract F. H. Entz Waterloo.—p. 78

Hodgkin's Disease—White and Senty report two cases of Hodgkin's disease and state that the disease is primarily a lymphoid hyperplasia, which is gradually superseded by granulomatous changes. It has invasive, erosive and metastasizing capabilities by which any tissue in the body may become involved. Primary predominant involvement of the retro-abdominal and thoracic lymph nodes often presents a pyrexial syndrome with chills, high fever and prostration followed by periods of comparative well being. Pruritus with or without apparent skin lesions may antedate other systemic symptoms by weeks or months. Diagnosis rests on remembering this pyrexial clinical entity, roentgen disclosure of unusual masses or bone involvement, and finding a favorable gland for biopsy together with diagnostic exclusion of other diseases that suggest themselves. The blood picture is essentially normal until secondary anemia develops. Sometimes eosinophilia is present. This is suggestive especially in the presence of recurring high temperature and chills. The etiology is unknown. Roentgen treatment and general supportive measures often give symptomatic relief for a time and prolong life. All cases are fatal.

Hyperplasia of Thymus Gland in Infants—Perley states that the symptoms produced by hyperplasia of the thymus are disturbances of respiration such as noisy respiration, dyspnea, retraction of the intercostal spaces and cyanosis. There may be digestive disturbances, vagotonic in origin as regurgitation and symptoms of pylorospasm. There were four boys and six girls in his series of patients, with an average age of 39 months (the youngest, 18 days). Seven gave an excellent response to treatment varying from a marked regression of symptoms following irradiation to complete relief after two treatments. Three did not respond. The 18 day old infant died of intussusception eight days after the first treatment. This child had a greatly enlarged thymus and the principal symptom was marked pylorospasm producing retching and vomiting. The author concludes that the following pathologic observations should be considered and excluded before a definite diagnosis is determined: foreign bodies in the air passages, obstructive specific laryngeal and retrotracheal abscesses, adenoids, atelectasis and any other unusual collapse of soft tissue. When none of these are found one must keep in mind whooping cough, meningitis and congenital heart and recurrent laryn-

geal nerve paralysis. The latter complication may remain producing symptoms even after the thymus has been reduced. Hyperplasia is a definite entity. When symptoms of thymic pressure are present, a rapid shrinkage of the enlarged gland and a marked relief of symptoms follow irradiation.

Gonad-Stimulating Principle of Anterior Lobe of Pituitary Body—According to the experiments of Van Dyke and Wallen Lawrence, the gonad-stimulating principle of the pituitary body retains its activity for five months if kept at 4°C in aqueous solutions at pH 3.7 to 6.4. Alkaline solutions of the hormone (pH 7.5) are stable for at least two and a half months. Purified preparations in aqueous solution (pH 4.9 to 5.4) are destroyed by boiling. Berkefeld filtration of aqueous solutions at either an alkaline or an acid pH does not remove the hormone. No evidence for the separation of the hormone into follicle-stimulating and luteinizing fractions was obtained. The experiments of Fevold, Hisaw and Leonard were not confirmed. In preparing pressor-free extracts the authors use powder made from acetone-dehydrated whole pituitary bodies of sheep. To x Gm. of powder they add 20 cc. of freshly standardized 0.02 normal solution of ammonium hydroxide. The mixture is then shaken occasionally and allowed to extract at room temperature for twenty-four hours. The pH of the mixture falls to between 9 and 10. Without separating the undissolved solids they lower the pH to within the range pH 5.0 to 5.6 by the use of glacial acetic acid, and after equilibrium is reached at this pH the supernatant fluid is removed by centrifugation. The residue is then washed in two instalments with enough acetate buffer of appropriate pH to make the combined volume of the supernatant fluid and washings equal to 20 cc. To this solution, enough 95 per cent ethanol is added to bring the ethanol concentration to 35 per cent by volume. The precipitate is allowed to flocculate at room temperature and after settling most of the supernatant fluid is removed by decantation. The precipitate is collected by centrifugation and washed with 35 per cent ethanol. To the combined alcoholic supernatant fluid and washings more ethanol is added in a quantity sufficient to make an ethanol concentration of 70 per cent by volume. The white flocculent precipitate that forms is allowed to settle over night. The precipitate is collected and dried by repeated washings with absolute ethanol and anhydrous ether. It is further dried to constant weight in vacuo at room temperature. The yield is about 27 per cent of the weight of the original sheep powder. This powder contains the gonad-stimulating principle, free from any pressor activity. Gonad-stimulating powders obtained from the pituitary are free from manganese. Manganese in total doses of from 10 to 0.1 mg. of hydrate manganese chloride causes no precocious sexual development.

A New Local Anesthetic—Rider states that diothane, the hydrochloride of piperidinopropanediol diphenylurethane, is a new local anesthetic that promises to be of great value. Its maximum toxicity as tested by rapid intravenous injection is

three times that of procaine hydrochloride, although it is less toxic than procaine hydrochloride on subcutaneous injection. The anesthetic activity on mucous membrane surfaces is more than double that of cocaine. When injected, diothane is about three times as active as procaine hydrochloride. Anesthesia with diothane is followed by a period of postoperative analgesia that appears to be unique to this compound among the available local anesthetics. Diothane solutions are nonirritating, stable and boilable. Clinical results that bear out the pharmacologic observations will be reported later.

Endothelioma of Spleen—Caldwell reports a case of a massive primary malignant neoplasm of the spleen which is apparently of reticulo-endothelial origin. Metastases were abundant in lymph nodes, lungs and subcutaneous tissues together with numerous peritoneal implantations. The liver was free of metastases except for a single nodule in its capsule. The tumor was of the large round cell type, with a tendency toward alveolar arrangement but without any definite angio-plastic structure. Delicate argyrophil fibrils seemed to be formed by the tumor cells in the more differentiated portions of the tumor, but they were almost completely lacking in the more cellular areas. The tumor is considered to be a primary reticulo-endothelioma of the spleen.

Progressive Pseudohypertrophic Muscular Dystrophy—In treating sixteen patients presenting progressive pseudohypertrophic muscular dystrophy, Voshell gave 1,529 doses of pilocarpine and epinephrine, 190 doses of glycine (glycocol) alone, and 115 doses of the two administered simultaneously. From thirty to sixty doses were required before any changes were noted. The pilocarpine and epinephrine method of treatment is simply the subcutaneous injection of from 0.2 to 0.3 cc. of 1,000 epinephrine hydrochloride and from 0.1 to 0.2 cc. of a 1 per cent solution of pilocarpine hydrochloride daily or every other day, up to sixty doses without interruption. The glycine method is to feed the patient a daily quantity of 5 Gm. of glycine for eight periods of three months each, three weeks intervening between the periods. The author obtained better results with the pilocarpine and epinephrine method. No large series has been treated with glycine so that its value is still to be tested although the cases shifted from pilocarpine and epinephrine to glycine showed decided retardation signs. The idea that the combined method might offer better advantages by giving the muscles more food (glycine)

to replace the lost creatine and by stimulating their autonomic nerve supply with pilocarpine and epinephrine has not as yet proved anything either way. It is probable that studies of the phosphocreatine metabolism will present some better preparation, which will act on a sounder physiologic basis. The fact that some patients have been apparently improved and some held stationary is at least worth while and gives a basis for the continued use of the method clinically with the hope that refinements will be forthcoming. The patient should not be put to bed for any cause, unless it is absolutely necessary, as the stimulation of muscle activity is essential to the retention of a minimum of function. The patient rapidly retrogresses under rest.

Treatment of Vincent's Tonsillitis—It is McHenry's custom to consider a diagnosis of Vincent's infection of the tonsil confirmed when the lesions respond within twenty-four hours to treatment with copper sulphate and sodium perborate. When they do not respond he resorts to smears, cultures and dark field examinations. If the history and clinical examination suggest diphtheria or syphilis or an acute pyogenic or streptococcal infection, he uses the microscope and the culture tube. To justify this procedure the author collected his last forty cases of Vincent's tonsillitis and studied them in regard to history, clinical appearance and response to treatment. The average amount of time required for the relief of symptoms was two days. Eleven patients were relieved of symptoms in one day, and one required four days before local relief was obtained. The average amount of time required for the disappearance of local swelling was 2.4 days. Complete disappearance of the membrane was achieved in the average time of 4.6 days. Four patients required only two treatments each, four had seven treatments each, and one had ten treatments. There were nine recorded recurrences in six patients. In employing this procedure in Vincent's tonsillitis the author removes the necrotic debris and the membrane, which separates easily, by a mild alkaline spray and gentle wiping with a cotton-tipped applicator. He applies a 10 per cent aqueous solution of copper sulphate to all ulcerated surfaces. This should reach the depths of all pockets and infected crypts. This procedure is repeated every day until the signs of acute inflammation have disappeared and every second day until the membrane has disappeared completely. The patient is given a prescription for sodium perborate and instructed to use one-half teaspoonful in half a glass of warm water as a gargle and mouth wash every two hours.

Arteriolar Changes in Essential Hypertension—Pilcher and Schwab studied fifteen cases of hypertension with complete necropsy protocols. All subjects were Negroes with one exception, a factor which merits consideration in view of the fact that in the Negro hypertensive disease tends to run a more rapid and fulminating course than in the white race. There were twelve men and three women. The ages varied from 21 to 71 years with an average of 45.7 years. In the fifteen cases examined, a decrease in the wall to lumen ratio was

found in each instance involving every tissue with the exception of the myocardium. The exact nature of the lesion producing the disturbance of the wall to lumen ratio varied in the different tissues. The average ratio of the wall to the lumen in the kidney was 1:1.13. The predominant pathologic changes were those of degeneration, fibrosis and hyalinization. Degenerative and fibrotic changes were only rarely seen in the liver although the wall to lumen ratio was uniformly altered the average being 1:1.08. The increased thickness of the vessel walls was practically always due to muscle hypertrophy evidenced by a considerable increase in the number of muscle nuclei. The arterioles in the pancreas showed significant changes in all but two cases the average wall to lumen ratio being 1:1.14. Here sclerotic and hypertrophic changes participated equally as a cause of thickening of the vessel walls. The greatest disturbance of the wall to lumen ratio was observed in the spleen 1:0.74. In the control cases the ratio was 1:1.29 an observation which justifies the conclusion that hypertension produces changes in the arterioles of the spleen, just as it does in other organs. The average wall to lumen ratio in the myocardium was within normal limits, 1:2.04. Four cases in the series showed a slight disturbance of the ratio ranging from 1:1.31 to 1:1.63 which in comparison to the other tissues was rather an insignificant change.

Purulent Pericarditis—Walker states that pericarditis with effusion, serous or purulent is a complication that occurs more frequently than has been generally thought. He feels sure that he must have had more than his two cases one of which he reports of serous and purulent pericarditis in his practice that he failed to diagnose. A more painstaking observation should be made in the daily examination of patients particularly those ill with pneumonia and rheumatism children acutely ill with scarlet fever and still more especially those with empyema of the pleura, and the rheumatic patient who becomes suddenly critically ill. If an effusion is diagnosed and it is serous it can be aspirated. The point of puncture should be in the fifth interspace about 1½ inches to the left of the sternum. After the needle has penetrated the chest wall, its base should be depressed so that the point remains near the chest wall and is less likely to injure the heart. If purulent effusion is diagnosed pericardotomy should be done with resection of the sixth costal cartilage. Nothing would be gained by aspiration and damage might possibly be done to the heart with the needle. A local anesthetic is to be preferred. It is said that ether and pus make a lethal cocktail in proportion to the amount of ether used and the amount of pus present. This is especially true when the pus is in the chest.

Thoracoplasty—Avelrod points out that all great statistics of operative treatment in tuberculosis of the lung are practically the same: one third healed, one third improved and one third failures. These equalities prove that the principle of the operation is correct and also that small technical variations are not important but that the most important factor is to be found in the compression of the lung. He believes that the indications for thoracoplasty are (1) in severe unilateral especially productive cirrhotic, cavernous tuberculosis if no considerable improvement can be obtained by any other therapy (2) when pneumothorax treatment is impossible in medium severe progressive, more or less unilateral at the most subfebrile partly caseous lobular tuberculosis (3) if pneumothorax is incomplete because of adhesions partial thoracoplasty may be done above the adherent part of the lung (4) in all pneumothorax empyemas and (5) in repeated hemoptysis when pneumothorax is impossible and phrenicotomy is unsuccessful. The contraindications are in widespread disease of the other lung, lung diseases with high fever, lobular tuberculous pneumonia, chronic nontuberculous changes of the other side, decompensated myocardial heart diseases, severe tuberculous infection of the kidney, bones and intestine, nephritides and nephroses, diabetes and in patients under 18 years of age and over 40, when the duration of the tuberculous process is longer than five years and when clubbing of the fingers is present as a sign of chronic intoxication.

Retrodisplaced Uterus—Crosthwaite believes that a considerable range of motion, especially backward, may be considered within the range of normality when considering the retrodisplaced uterus. Any disease or condition that holds the

uterus fixed in any one position must be considered pathologic. Any operative procedure that fixes the uterus immovably in any one position is unsurgical, fundamentally wrong and detrimental to the future welfare of the patient. Any operation or technic potential of causing intestinal obstruction, such as the old ventral fixation should be abandoned. If the round and broad ligaments are used to elevate and maintain the retrodisplaced uterus a technic must be used which will not interfere with the blood and nerve supply of the ligaments and contiguous parts. In an operation for the correction of the retrodisplaced uterus, the symptoms for which the patient seeks surgery should be relieved the uterus must not be fixed immovably in any one position and the possibility of post-operative intestinal obstruction must be obviated. A procedure that interferes with or perverts the physiologic functions or disturbs the normal anatomic relationship of the uterus and its adnexa must be regarded as unsurgical and inadequate.

*Bandl's Contraction Ring V. E. Dudman Portland Ore.—p. 101

Suppurative Pericarditis—Cottam believes that, in draining the pericardium, the requirements are best met by removal of a section of the right fifth costal cartilage incision into the underlying pericardium and insertion of a long piece of flexible rubber tubing between the heart and the pericardial wall obliquely upward and to the left posteriorly. He gives a report of a patient in whom he used this method. The most comfortable position the patient assumed was when lying on his right side and then the flow was directly downward. The sepsis gradually abated without exacerbations. The cardiac function improved from the start. The patient recovered completely. Suppurative pericarditis, being always secondary to some other serious disease is in itself always a serious problem. The hazard is increased by the impossibility of early diagnosis and the fact that many diagnoses are overlooked even in larger effusions. The death rate is high. The treatment is purely a matter of adequate surgical drainage with the least interference and the utmost conservation of a desperately ill patient's resources. No drainage can be considered adequate if it does not provide for the evacuation of the deeper recesses of the pericardium. This is best accomplished by a right-sided approach, preferably through the fifth costal cartilage fairly close to the sternum. Through this the internal mammary vessels may be tied the pleura displaced outward and the pericardium back of the heart easily reached with a tube, through which dependent drainage can be secured with slight change of posture.

Bandl's Contraction Ring—Dudman points out that early rupture of the membranes is an etiologic factor in Bandl's contraction ring though early rupture commonly is secondary to disproportion or malposition. Prolonged labor particularly in elderly primiparas labor in the neurotic type of patient, and stimulation of the first stage of labor by urging the patient to employ effort during the first stage, or by administration of solution of pituitary have all been noted as etiologic factors. The location of the ring in the order of its frequency is around the neck, 45 per cent, the body, 21 per cent, the arm 15 per cent, the thorax, 9 per cent, and the neck of the after coming head, 9 per cent. It is important to conduct the average case of dystocia in such a manner as to avoid a contraction ring. The frequent occurrence of the condition is evidence of failure to apprehend the causation. Relaxing drugs with the exception of epinephrine and possibly amyl nitrite are of little value. Early recognition, with the employment of cesarean section is a desirable treatment and may serve to avert the undesirable procedure of embryotomy.

Achlorhydria and Dysentery Observations on Test Meals of One Hundred Postdysenteric Cases T E Camps—p 123

Gastric Secretion in Achlorhydric and Allied Anemias—Hartfall and Wits report the results of fractional test meals in 137 women with idiopathic microcytic anemia, and of histamine tests in 39 of these cases. Apparent achlorhydria or extreme hypochlorhydria was present in nearly 80 per cent of the cases and true achlorhydria in more than 50 per cent. The achlorhydria is not the result of the anemia. The possible etiologic factors in achlorhydria in the order of their importance are heredity, the action of hematogenous toxic agents on the stomach, operative or other trauma to the stomach and gastritis from direct irritation of the stomach. In a significant number of the authors' cases the gastric secretion was deficient in total chlorides and contained no free hydrochloric acid and little or no pepsin. It was indistinguishable by ordinary tests from the gastric secretion in pernicious anemia. Nevertheless it is unusual for these women to develop pernicious anemia.

Bronchial Infection in Asthma—Knott and Thornton discuss the occurrence and nature of the bacterial infections occurring within the bronchioles of 333 asthmatic patients. Out of the total of 333 cases 208, or 61 per cent, showed noninfected, strongly eosinophilic sputum and gave a history of allergy either in themselves or in their families. 120 or 37.5 per cent showed bronchial infection but they also had quite obvious eosinophilic concentration in their infected bronchial plugs as well as a clear cut history of allergy in themselves or in their relations, and five or 1.5 per cent had sputum with plugs showing a heavy bacillary infection which produced a positive histamine like response, but no eosinophilia, no positive cutaneous reaction to any allergens and no personal history of hypersensitiveness could be obtained. The authors suggest that in view of the relative rarity in asthmatic patients of any demonstrable true sensitization to bacterial proteins the effect of bronchial infection is produced mainly by direct stimulation of the bronchial muscle by substances similar to those present in bacillary cultures. They describe methods for detecting the organisms involved together with the characters of the sputum containing them. From an analysis of their patients' case records it is shown that 1. These bronchial infections have a definite seasonal incidence

during the summer months and persons suffering from asthma are somewhat more likely to show infection than those not affected. 2. Juveniles are much less likely than adults to show bronchiolar infection, this being apparent in all types of infection. 3. Foci of infection not infrequently may be found in the nose containing organisms of the type capable of producing histamine-like substances. The authors emphasize the importance of eradicating such foci in asthmatic patients.

Skin Reactions of Asthmatic Patients—Pearson carried out an investigation in a series of fifty asthmatic patients and fifty normal controls in order to determine the immediate dermal responses to urinary 'proteose' and in the event of obtaining positive reactions to correlate them with dermal responses to peptone, histamine and protein, and to determine the clinical significance of the observations. He found that 1. Asthmatic patients tend to give nonspecific skin reactions with solutions of protein or protein derivatives containing from 10 to 20 mg of nitrogen per hundred cubic centimeters. This tendency was present in a much smaller degree in the healthy control group. 2. After allowance was made for this tendency patients suffering from asthma gave significant reactions to their own urinary proteose in 38 per cent of the cases. In 24 per cent reactions occurred to the 1:100,000 solution containing from 0.1 to 0.2 mg per hundred cubic centimeters. 3. If the asthmatic series is subdivided into those cases showing specific reactions to individual protein substances (foods or inhalants) and those in which no protein sensitiveness was demonstrated, the former group gives significant reactions in 50 per cent of the cases to their own proteose whereas the latter gives 15 per cent of positive reactions. 4. The control series being similarly tested with their own proteose only 2 per cent gave significant reactions to their own proteose in the 1:1000 solution. 5. Solutions of asthmatic proteose produced significant reactions in 32 per cent of the control subjects. 16 per cent reacted to the 1:100,000 solution and one half of these had allergic family histories. 6. The dermal response to histamine is remarkably constant in normal and asthmatic persons. 7. The skin reactions to proteose are not due to histamine. The evidence is in favor of the reaction being due to some unidentified toxic substance. The possibility of allergic individuals being actually sensitized to such a toxic substance has not been definitely disproved.

Sulpharsphenamine in Treatment of Syphilis—Denham-White and his associates made a comparative study of the value of sulpharsphenamine in the treatment of syphilis by using sulpharsphenamine, sulpharsphenamine and metallic bismuth, neoarsphenamine neoarsphenamine and metallic bismuth, neoarsphenamine and disodium hydroxymercurosalicyloylacetate, arsphenamine and dextrose and sodium bismuth thioglycollate. They observed that sulpharsphenamine is a most efficacious drug in the treatment of syphilis and its manifestations and is better tolerated than any other arsphenamine compounds. The largest number of cases showing a negative Wassermann reaction after treatment was noted in the case of sulpharsphenamine. Among the clinical advantages noted by the authors in cases treated with sulpharsphenamine are absence of reaction, no rise in temperature, absence of pain, no nitritoid crises, no anaphylactic conditions and heretofore no arsenical dermatitis. The drug may be regarded as one of the most innocuous at present in use, its lack of toxicity being most marked in comparison with its high efficacy. It appears to be most suitable for both hospital and private use. The rapidity with which symptoms disappear compares favorably with that obtained by other preparations. The authors experience in

their hospital is that the ordinary Indian female patient is intolerant of neoparsphenamine in doses of more than 0.45 Gm., and it is their practice never to exceed this. The usual onset of dermatitis when it occurs, is after the fourth injection or if the dose of 0.45 Gm. has been exceeded. With sulpharsphenamine the maximum dose has been up to 0.6 Gm. without the slightest untoward effect. It is to be remembered that the dosage of the arsenical compounds, such as neoparsphenamine has been based on the physical characteristics of the European and it is now known that Indian women cannot tolerate a dose well borne by European women. This does not, however, seem to apply in the case of sulpharsphenamine. No instance has been observed in which the Indian woman has shown intolerance even for the higher doses. It therefore appears clinically that it is of a comparatively low toxicity.

*Treatment of Tuberculous Cavities of Lung. L. S. T. Burrell.—p. 356

Recurrent Pyogenic Parotitis—Payne has studied nineteen cases of recurrent pyogenic parotitis. It is characterized by recurrent swellings of one or both parotids even at times in the more chronic cases involving the other salivary glands. In some of the author's patients the commencement of parotitis dates from an acute dental infection, a severe tonsillitis or a sinus infection. At times beginning the use of dentures or neglect to keep these adequately cleaned has been responsible. The accurate diagnosis of recurrent pyogenic parotitis depends on a careful history and a thorough examination of all the salivary glands, their ducts and their orifices. A catheter specimen of saliva should be collected from the affected gland (it is not always possible to do this in the case of the submaxillary glands), and this should be examined for its cytology, bacteriology and ptyalin content. Roentgenograms of the affected region should then be taken, which in the case of the submaxillary gland should include both intra-oral and extra-oral films, to exclude the presence of a calculus and finally sialography should be performed, when practicable, to determine the site and severity of the pathologic lesions of the ducts and to serve as a guide to treatment. Mumps stone, Mikulicz's disease, uveoparotitic polyneuritis, preauricular lymphadenitis, mixed parotid tumor and malignant disease of the parotid are conditions that should be differentiated from recurrent parotitis. The first principle of treatment is to keep the ducts of the parotid patent and to keep the region of the duct orifice in the mouth as free from infection as possible. Any obvious cause of sepsis in the mouth particularly in the region of the affected parotid duct should be dealt with especially infected teeth. Massage of the parotid is by far the most important single item in the line of treatment. If duct obstruction can be avoided, one can certainly say that the development of recurrent attacks of parotitis will also be avoided. By means of iodized poppy-seed oil injections of grossly diseased parotids it is possible to empty the main duct and its branches after even a few seconds' massage of the gland. Patients should be instructed to carry out prophylactic massage of the parotid. The juice of half a lemon in a little water will cause an intense flow of saliva, removing any possible stagnation caused during the night. This should be done immediately after massage. Operation is rarely necessary, but it may be indicated when the condition is severe or when it has failed to respond to other treatment carried out efficiently. It may consist in (1) dilation of the parotid duct, (2) slitting the orifice of the parotid duct, followed by dilation or (3) avulsion of the auriculotemporal nerve. During the actual exacerbation of the disease there is always either complete or partial obstruction of some portion of the duct system often the main duct. Immediate treatment thus consists in the relief of obstruction and is identical with that which should be under-

taken from the outset in any case of acute pyogenic parotitis, whether recurrent or not.

Treatment of Tuberculous Cavities of Lung—Burrell states that a tuberculous cavity in the lung is a potential danger and its treatment is not without danger. Consequently, the patient should not be exposed to a treatment that is more dangerous than the cavity. The annular shadow often shown by radioscopic examination of tuberculous lungs is probably due to a cavity in the majority of cases. In the absence of any symptoms or signs other than those of radiocopy, this type of cavity is not an indication for any special treatment. A dry cavity in a chronic fibrotic case is best treated by the same means as a chronic fibrotic case without cavity. Attempts to close the cavity by pneumothorax or thoracoplasty are usually unsuccessful and often shorten the life of the patient. When a cavity is accompanied by much expectoration, special treatment is indicated, because the disease is likely to spread and the prognosis is bad. Artificial pneumothorax should be tried first and adhesions divided if necessary. Failing this, phrenic avulsion and thoracoplasty or apicolysis may be tried, but if these methods are contraindicated the lung should be rested by the application of sandbags to the chest wall. Apicolysis is more successful than a partial thoracoplasty. In the acute case with cavity formation, artificial pneumothorax is the best treatment. Failing this, the lung should be rested by sandbags. Phrenic avulsion and thoracoplasty are contra-indicated.

*Hypoglycemia: Survey and Account of Twenty-Five Cases. C. Sippe and J. Bostock.—p. 207

Some Useful Tests in Diagnosis of Common Clinical Conditions. Ethel Byrne and Ruby Beveridge.—p. 218

Hypoglycemia—Sippe and Bostock believe that, in the study of cases of hypoglycemia, it is important to perform a dextrose tolerance test in preference to a single fasting dextrose test. The reason for this statement was borne out in several of their patients in whom there was a normal fasting dextrose but a low figure at the end of from one and a half to two hours. The most feasible explanation of this phenomenon is that the patient's nervous tension is naturally increased and the fear mechanism brought into play. Hypoglycemia, with its attendant train of symptoms, is to be regarded in the light of a metabolic disturbance due to many causes. Just as pyrexia alone is often treated with advantage to the patient, so does the treatment of hypoglycemia alone aid in improving the patient's well-being. A short course of dextrose medication may be sufficient to alter the situation by breaking those widespread vicious circles which create such a vivid and varied symptomatology in both acute and chronic disease. In the majority of patients a careful search will reveal other defects that need systematic attention. In the cases described by the authors are included a number of somatic disturbances, including endocrine maladjustment. Septic foci should be attended to, and a regular action of the bowels obtained. Half an ounce of dextrose may be given alone or in an orangeade usually a night and morning dose is sufficient, but in some cases an extra dose may be given during the day. Barley sugar or boiled sweets are just as effective and are preferred by most patients, especially children, the usual amount being from 3 to 4 ounces daily. It is of advantage to encourage the patient to eat between meals. In cases of acidosis it is necessary to restrict fats, especially butter, and to allow eggs only in small numbers. The authors stress the fact that hypoglycemia is a condition and not a disease.

Gravidic Endometrioma of Abdominal Wall—Martin and his associates report a case of gravidic endometrioma. In a woman, aged 37, who had undergone a cesarean section eight years before, they discovered in the course of a new pregnancy a parietal tumor which was a fistulized endometrioma. The biopsy of the tumor totally extirpated in a second cesarean section, confirmed the diagnosis of endometrioma of the abdominal wall. It exhibited a marked and diffuse decidual reaction. The authors think that what appears to be a uterine fistula is frequently a fistulized endometrioma of the abdominal wall. The presence of decidual cells in a tumor located in the cicatrix of a laparotomy is the result of a pregnancy in evolution and is an argument in favor of the sexual origin of endometriomas.

Osteogenic Sarcoma Treated by Roentgen Therapy C. Guibert and
A. Tardieu—p. 302

Osteomyelitis of Scapula—Guibal and Montagne think that the difficulties of diagnosing acute hematogenous microbic infection of the scapula result from the complex anatomy of this bone. In studying the development, form and topography of the scapula, one is struck by its multipolar ossification, ten dispersed centers of ossification spreading over its surface, its complex conformation, projections, partitions and ledges outlining fossas and cavities which completed by bands of muscle, layers of fascia or capsular envelopments lead in various directions and its multiple connections, which converge on the cervical, dorsal, thoracoparietal, axillary and scapulohumeral regions. From these characteristics arise the multiplicity and dispersion of the centers of osteomyelitis, the canalization of the suppuration originating in the ossification centers, and the clinical manifestation of the inflammation at the level of the bordering regions. Osteomyelitis of the scapula may manifest itself under the aspect of a supraspinous inflammatory focus spreading toward the neck, an infraspinous focus spreading toward the back, a subscapular focus extending toward the thoracic wall, an articular focus invading the scapulohumeral articulation or an axillary focus involving the axillary cavity, finally, the inflammation may infiltrate the entire region of the shoulder if the osteomyelitis is multipolar or total. It is important to know these misleading manifestations, when suspecting scapular osteomyelitis, in order to choose the appropriate route of access to the osseous lesion.

Postoperative Reaction in Hyperthyroidism—The older conception that the postoperative reaction in thyrotoxic patients was caused by the introduction of unusually large amounts of thyrotoxic products into the circulation found support in the fact that the pulse and the basal metabolic rate were increased

in these patients. Rahm calls attention to the fact that Bier and Roman found in the blood of such patients a lowering of iodine and of other thyroid components. This suggests that the opposite cause may be responsible for the reaction, namely, a sudden deprivation of all thyroid secretion. The author studied basal metabolic rates in forty patients after operation in order to throw further light on its relation to specifically thyrotoxic reaction. He found that the basal metabolic rate rose in all twenty-three cases of thyrotoxicosis, the average rise amounting to 16 per cent. In twelve patients operated on for simple goiter, an average rise of 20.5 per cent was shown. The same observations were recorded for patients who were operated on for conditions having nothing to do with the thyroid gland, the average rise amounting to 16 per cent. These rises in the basal metabolic rate corresponded accurately with the postoperative rises of temperature. The author concludes that the rise in metabolic rate is not due to a postoperative hyperthyroidism. In his material the rise in thyrotoxic patients was somewhat lower than in other conditions, suggesting that possibly the preoperative treatment with iodine desensitized the patients.

Treatment of Patellar Fractures and Posttraumatic Arthritis Deformans—Friedrich compares the results obtained in the treatment of patellar fractures with separation of fragments during the period up to 1923 with those obtained since that period. While conservative treatment was given preference up to 1923, most of the fractures in the latter group were treated surgically. In the majority of the cases, circlage of the patella was the operation of choice. A follow-up study of seventeen conservatively treated fractures of the patella with separation of fragments and of forty patients operated on revealed that normal function of the knee joint was obtained in 60 per cent of the former and 90 per cent of the latter. An ideal functional result was obtained in more than 50 per cent of compound fractures of the patella all of which were treated surgically. Operative treatment yielded a bony union three times as often as did the conservative method. Factors favoring the development of arthritis deformans after a patellar fracture are trauma, effusion of blood into the joint, prolonged immobilization of the joint and improper healing of the fracture. The condition developed twice as often in conservatively treated patients.

Henle-Albee Operation in Tuberculous Spondylitis—Bauer and Jenner present an analysis of eighty-four cases of tuberculous spondylitis treated at the Göttingen clinic by the Henle-Albee operation. The aim of the study was to determine the end-results as seen in the roentgenogram and the question of deformity as well as of ultimate cure. The patients were followed up for from six to sixteen years. The authors state that the operation can be considered only in cases in which the outlook for a cure under conservative management is quite good. They point out that the operation does not remove the diseased focus, that a certain amount of damage to the focus is unavoidable, and that the operation cannot prevent deformity of the diseased adjacent vertebrae. The late results are, if anything, somewhat inferior to those obtained by the conservative management in cases of the same age and of the same gravity. In their opinion, the operation has failed to meet its indications. It has not been performed in their clinic in the last six years.

Changes in Blood and in Water Content in Experimental Ileus—In his animal experiments, Brandes found that morphine-ether narcosis produces concentration of the blood analogous to that produced by hunger and thirst in experimental ileus. He found that the severity of the course in high intestinal obstruction and the corresponding blood concentration depended on the degree of damage to the intestinal wall and on the rate

of absorption from the obstructed intestine. When the venous circulation of the intestine was interfered with the course was less rapid. It thus appeared as if the severity of the course and the death of the animal depended on the absorption of some toxic material from the obstructed intestine. This in the author's opinion lends further support to the intoxication theory of death in high intestinal obstruction. It was also found that the less shock accompanying the course, the more capable were the tissues of compensating for the loss of water and of chlorides. Next to the loss of chlorides that of water appeared to be more important than the rise of albumin content in the blood. The author regards the latter as the result of loss of water. He suggests that the loss of chlorides and of water is to be made up before the operation by the intravenous administration of hypertonic salt solution say from 20 to 30 cc of a 10 per cent solution of sodium chloride and by subcutaneous administration of physiologic solution of sodium chloride. Red cell count and hemoglobin determination offer quick information as to the state of concentration of the blood and the degree of damage done to the circulation.

Icterus Simplex.—Von Haberer points out that simple icterus, ordinarily treated with success by the internist, may assume a severe form with acute or subacute liver atrophy. Such cases suggest an obstructive lesion by a tumor or a gallstone and are accompanied by symptoms of severe cholangitis. In this type of cases, biliary drainage in its simplest form by cholecystostomy, brings about a cure. The author suggests that this treatment be combined with a continuous intravenous drop infusion of dextrose and insulin and some dehydrocholic acid. In the severest forms of this condition, one finds white bile in otherwise normal and patent extrahepatic biliary tracts. Even patients operated on in a state of coma may still be saved if secretion of bile sets in after the operation. Of the seventeen patients operated on by the author sixteen have recovered. One patient had a genuine recurrence of the sickness but recovered with medical treatment. The operative method is suggested for severe cases in which in spite of the medical treatment failure of liver function is imminent. The operative results thus far have been encouraging.

Results of Removal of Injured Spleen.—Bremer reports eleven cases of traumatic rupture of the spleen observed in Haberer's clinic (Cologne) during the last sixteen years. In only one case could the hemorrhage be controlled by suture of the splenic capsule, and the spleen had to be removed in ten cases. Of these, six were observed for periods of from one to sixteen years. The author points out the high incidence of postoperative pulmonary complications, such as pneumonia and bronchopneumonia. Anomalies of the blood picture were found in practically all of the cases. They exhibited neutrophil leukocytosis, monocytosis or eosinophilia. Two cases showed high hemoglobin and a high red blood count, one approaching clinically the picture of polycythemia but yielding to treatment with splenic extract. One healthy female patient developed a bilateral tuberculous involvement of the lungs several months after splenectomy. This gave the impression that the loss of the spleen was responsible for her loss of resistance. The frequent postoperative pulmonary complications observed may be attributed to the same cause.

Esophageal Carcinoma.—Dehne calls attention to English statistics according to which there were 15,909 fatal cases of esophageal carcinoma between the years 1911 and 1920. Of all the cases of carcinoma, 9.7 per cent occur in the esophagus, placing it next in frequency after carcinoma of the stomach, the female genitalia and the intestine. Investigation of 300 cases by Broders at the Mayo Clinic disclosed that 90 per cent

of these belonged to a highly malignant, rapidly progressive type. The rapid progression of the growth and the high operative mortality (92 per cent of F. Thorek's material) make it appear that the palliative treatment directed toward the relief of dysphagia has more to offer than the radical operation. The author considers Plummer's method of dilation by a sound threaded over a swallowed silk thread superior to all other methods. The results obtained are likewise superior to those obtained by a gastrostomy. The author treated nineteen patients by the method with gratifying results. He had no immediate mortality from it. Vinson's immediate mortality with 504 patients amounted to 0.6 per cent. Improvement in deglutition after a single treatment persisted for from ten days to five months. The average duration of life amounted to seven and seven-tenths months. On the basis of Vinson's and his own experience, the author concludes that this is the safest of all methods of dilation, since it obviates perforation. It is valuable for differentiation of cardiospasm and of esophageal diverticulum. The stenosis can be overcome to a greater degree than with other methods. It requires no hospitalization and no especial training. It makes possible a bioscopy without recourse to the somewhat dangerous esophagoscopy for small amounts of tumor tissue sufficient for histologic examination can be recovered by the passage of the sound.

Action of Injectable Liver Extracts on Blood.—In nineteen patients with pernicious and secondary anemia, or with diseases of the liver or of the biliary passages and in persons without clinically demonstrable changes of the blood-forming apparatus and of the liver, Gebhardt and Klein observed that parenteral administration of liver extracts was always followed by a noticeable increase of the cholesterol and of the cholesterol ester contents of the serum. The cholesterol values were determined partly by gravimetry and partly by colorimetry. As far as the influence on cholesterol is concerned, injectable liver preparations do not differ from fresh liver or from enterally administered liver extracts. The authors consider a hormonal modification of the liver metabolism the cause of the increase in cholesterol content.

Influence of Thyroxine on Erythropoiesis.—Dambé points out that the blood picture of patients with exophthalmic goiter shows changes indicating an increased activity of the bone marrow, and he cites hematologists who are convinced that the endocrine glands, particularly the thyroid, play an important part in maintaining the physiologic equilibrium between the various links of the hematopoietic system. The fact that Unverricht had obtained favorable results with thyroid extract in anemias concurring with hypofunction of the thyroid induced the author to study the influence of thyroxine on erythropoiesis in a number of patients with anemia. He obtained favorable results in three patients with severe pernicious anemia. He found that thyroxine reduces the latent period before the liver extracts become effective and that stimulation of the bone marrow by thyroxine makes liver therapy efficient even in cases that are refractory to liver therapy. The action of thyroxine depends on the presence of a bone marrow still capable of regeneration, and for this reason it is not possible to influence anemias in the course of severe

leukemias or of carcinomas. The author recommends thyroxine as a valuable adjuvant in cases of anemia in which the latent period before the action of the liver extracts should be shortened, and also in anemias refractory to liver arsenic or iron therapy in which stimulation of the bone marrow by thyroxine favors a more rapid action of these remedies.

Antibody Reaction in Infectious Mononucleosis—Rosenthal and Wenkebach review the hematologic characteristics of lymphocytic angina, monocytic angina and infectious mononucleosis and describe the standard symptoms of infectious mononucleosis as well as the deviations from the typical course. Twenty-eight case histories illustrate that the symptomatology of various disorders may closely resemble the symptomatology of infectious mononucleosis. In cases in which the characteristic symptoms and hematologic changes are absent, the heterophile antibody reaction, which was introduced for the diagnosis of infectious mononucleosis by Paul and Bunnell is the only method that makes an exact diagnosis possible. The only other condition in which the heterophile antibody reaction has been observed is serum disease, and consequently the reaction can be recommended as an aid in the diagnosis of infectious mononucleosis. Investigations are now being conducted to determine why two such different diseases give the same positive reaction. The heterophile antibody reaction demonstrates that infectious mononucleosis is a disease entity differing from lymphocytic angina, monocytic angina and glandular fever.

Myoma and Pregnancy. Treatment of Pyemia and Interruption of Pregnancy—Von Franque reports the clinical history of a woman aged 41, in whom pregnancy was complicated by a painful tumor of the uterus. On the basis of former observations the tumor was thought to be a necrotic or an infected myoma. The operation revealed a necrotic myoma and a fetus deformed by compression. Although in the reported case an operative intervention was necessary, the author emphasizes that the pregnancy can be brought to term in the majority of cases of myomatosis of the uterus. Only serious manifestations justify an intervention during pregnancy and it should be directed against the myomas and not against the pregnancy. Interruption of pregnancy by way of the vagina is never advisable in myomatosis, because older statistics record mortality rates up to 41 per cent largely the result of retention and disintegration of remnants of ovum and of spreading of the infection to the myomas. The author relates two case histories. One case shows that even spontaneous abortion involves great dangers in myomatosis of the uterus and the other case is a typical example as to how near death a woman with myoma may come as the result of an induced abortion. The author's observations on pyemia prove that the uterus itself may be the focus of pyemia and that the veins are not necessarily involved, and he therefore considers Martens' demand for ligation of the veins too radical because many unnecessary interventions would be made if it were generally adopted. He shows that pyemia may even be cured without a surgical intervention and he thinks that the strengthening of the organism, so that it may combat the infection, is generally better than the early operation according to Martens. In discussing the methods of interruption of pregnancy he states that evacuation following simple dilation is best in the early stages, but, after the fourth month, he recommends anterior uterocolpotomy, the so-called small cesarean section.

Chromophil Cells of Hypophysis and Carbohydrate, Fat and Cholesterol Metabolism—The fact that acromegaly, now generally considered the result of eosinophil hyperpituitarism, concurs in more than 30 per cent of cases with diabetes mellitus led Kraus to assume functional relations between the hypophysis and sugar metabolism, and he investigated this problem in a large number of young patients with diabetes. In a great per-

centage of the cases he noted a decrease in the average weight of the hypophysis and also a decrease and a reduction in size of the eosinophil cells. The antagonism between the anterior lobe of the hypophysis and the insular apparatus of the pancreas which he assumed on the basis of his systematic morphologic studies on human subjects was corroborated several years later by experimental and clinical studies. These studies do not indicate what type of cells of the anterior hypophysis produce the substance antagonistic to insulin, but in view of the conditions in acromegaly and in diabetes mellitus the author thinks that the eosinophil cells are the ones that influence the carbohydrate metabolism. He advances evidence indicating that the basophil cells of the anterior hypophysis are related to the fat and cholesterol metabolisms. In this connection he discusses Cushing's pituitary basophilism and points out that the concurrence of basophil adenomas of the hypophysis with obesity, sexual dystrophy and increase of the blood pressure is not accidental but that close genetic relations exist between these conditions. He cites Reiss and Langendorf who observed a considerable increase of the blood cholesterol in rabbits and dogs following administration of the sex hormone of the anterior hypophysis. Since this hormone is produced by the basophil cells, it may be concluded that this type of cells is of importance not only for the sexual sphere but also for the cholesterol metabolism.

Pleural Empyema in Childhood—Brann reports experiences with 125 cases of pleural empyema in children (not including tuberculous cases), with special emphasis on therapy. While small empyemas, such as interlobar ones, received the customary conservative treatment, extensive empyemas in nurslings were treated by repeated aspirations. In children of more than 1 year of age, aspirations were repeated at intervals until the thickening of the secretion or the formation of fibrin clots made them useless or until it was seen that the treatment did not lead to the goal. During this period of not less than one week and not more than two, the acute manifestations recede, the bacteria lose their virulence, and fibrinous infiltrations and adhesions fix the position of the organs so that, when the pleural cavity is opened, mediastinal fluttering and circulatory disturbances can scarcely occur. Following this preparatory treatment, resection of the ribs was performed under local anesthesia with closed drainage. Respiration exercises against resistance were started soon after the intervention and were continued after treatment of the wound was concluded. The average duration of treatment was six and one-half weeks. Of sixty-four children operated on according to this method, including three nurslings, 89.1 per cent were cured and 10.9 per cent died. Significant deformities of the thorax and spinal column were not observed in the children in whom late examinations were made. These results encourage the indication for rib resection, after preparatory aspirations, even in nurslings.

Influence of Brine Baths on Metabolism—Meyer studied the effect of warm water, sodium chloride and brine baths on the mineral metabolism of six healthy children between the ages of 3 and 10, in two of them protein metabolism also was studied. By exact quantitative determinations of the proteins and minerals administered to each child during the test period and of the proteins and minerals contained in each specimen of urine and feces, the quantity of each substance retained was established. The protein metabolism was not changed by warm water baths while sodium chloride and brine baths increased the daily elimination of nitrogen. The sulphur metabolism was in a large measure parallel with that of protein. Only one of three cases exhibited a greater sulphur retention during the

influence of brine baths than in the preceding days despite increased protein decomposition. Phosphorus metabolism was not affected by warm water baths or by sodium chloride baths. During the influence of brine baths one of three children eliminated an increased amount of phosphorus while the other two retained it in greater degree. A regular dependence of the phosphorus metabolism on the protein metabolism could not be distinguished. The calcium metabolism also was unchanged by warm water baths. Sodium chloride baths in one case were without effect, in another case they increased the calcium elimination, and in a third case the retention was increased. Under the influence of brine baths there was in one case an increased calcium elimination, and in two cases an increased retention of calcium. The proportion of retained calcium to retained phosphorus was practically unaltered under the influence of warm water and sodium chloride baths. When brine baths were given, the proportion was altered in favor of the calcium.

Tumor Relapses—Bittorf reports two observations of late recurrence of malignant tumors after apparent cure. In the first case a melanoma appeared in the liver of a woman, aged 80, twenty-five years after removal of a melanosarcoma of the eye. The senile involution of the liver was probably the cause of the proliferation of the tumor cells till then restricted in their growth by natural forces of resistance. The author thinks that all cases of late metastases must be explained by the action of a defensive mechanism. In the second case eight years after radical operation of a carcinoma of the breast, a tumor of the hilus and a subcutaneous nodular exanthem appeared in addition to a pleuritis. The diagnosis was carcinomatous metastases. Six months of rest, overfeeding and high altitude sunlight treatment caused a complete disappearance of the tumor and exanthem as well as of the pleuritis, but several months later typical mammary carcinomatous metastases appeared in the oral mucosa, and further metastases caused death. In this case, the general therapy so strengthened the patient's resistance weakened by the pleuritis (possibly at first nonspecific), that the body was able to overcome the attack of carcinoma temporarily. This shows the advisability of employing all possible methods of increasing the natural resistance of the body as soon as possible after removal of the primary tumor, so that the fight against metastatic cells may be started early.

Salt Free Diet—Robert has achieved unusually good results with the salt free diet as prescribed by Volhard in a variety of diseases. This diet demands not only the omission of salt from foods prepared in the home but the use of unsalted bread and the omission of all milk preparations except diluted cream, smoked and pickled meat and so on, so that not more than 1 Gm of sodium chloride is secreted in the urine daily. Salt substitutes with organic anions and sodium, potassium, calcium and magnesium cations may be used. While its action is not fully understood, a salt free diet has a dehydrating effect, which reduces the blood pressure by decreasing the quantity of blood and of tissue fluids. The sodium ion has a water fixing and the potassium and calcium ions a dehydrating effect. These two electrolytes are especially abundant in a diet rich in fruit and vegetables. The aim of the salt free diet is thus a demineralization and transmineralization. Foremost among indications for this diet is cardiac insufficiency, of which three cases are reported. Another indication is cirrhosis of the liver. It is indicated in essential hypertension because it effects the greatest decrease in the total body fluids and puts the least burden on the heart, in nephrosis to reduce the edema, in diabetes insipidus

to relieve the polydipsia, and in certain cases of subacute and chronic nephritis. It is contraindicated in acute hemorrhagic nephritis. It has been used in angina pectoris and in epilepsy, especially in children. To achieve a permanent success with this diet it must be continued for a long time, but, as a rigid salt free diet if protracted too long may cause a uremia a little salt may be permitted from time to time. After an interval of a salt containing diet, a salyrgan injection should be given.

Aleukemic Diseases of Lymphatic System and Specific Granuloma—Sternberg says that in the last ten years there have been described under the name of reticulo-endotheliosis a number of cases of enlargement of the lymph nodes, tumors of the spleen and swelling of the liver which on a histologic basis, could not be classified with any of the well known groups of aleukemic diseases of the lymphatic system, namely, lymphosarcomatosis, lymphogranulomatosis and aleukemic lymphadenosis. From a study of these cases of so-called reticulo-endotheliosis he concludes that, with the exclusion of the genuine blastomas and the proliferations of reticular cells induced by storage of fat or lipoids, most if not all cases represent acute or chronic inflammatory processes localized primarily in the lymphatic system and accompanied by the formation of nodular granulomas, diffuse development of granulation tissue, or extensive hyperplasia of the reticular cells. This brings up the question why in these cases under the influence of inflammatory noxa probably of bacterial origin, granulomas of specific structure develop. The fundamental identity between the structure of granulomas developing around foreign bodies (silk thread, hair paraffin drop) and specific granulomas makes him think that the development of the specific granulomas must be attributed to the foreign body action of pathogenic bacteria of decreased virulence. In the course of a chronic infection the body, after acquiring a certain degree of immunity, can so weaken the toxic substances of certain pathogenic bacteria that they act on the surroundings essentially as foreign bodies. This explains the allergy of which the development of granulomas is considered a manifestation. The different formations exhibited by granulomas, which are specific for the etiologic agent, are determined by the different chemical compositions of the latter. This conception may also explain the cases of granulomatosis of the lymphatic system described as reticulo-endotheliosis which, while similar to lymphogranulomatosis, exhibit differences in tissue reaction indicating the action of different etiologic agents.

Modern Dietetics of Cardiac and Renal Therapy—Elias says that modern dietetic therapy in circulatory and renal diseases is based on the principles that the protein intake may not be reduced below a certain minimum higher with a predominantly fat diet and lower with a predominantly carbohydrate diet, without endangering the body proteins and that an increase or decrease in body weight can be achieved by control of the calories administered in the food. In severe circulatory disturbances with dyspnea, intense cyanosis and general edema, a two to three day fast is suggested to bring about dehydration. Rest in bed is required during the fast, and a few cups of black coffee or cognac may be permitted. A pap diet is then administered for a few days followed by a few days of vegetable diet poor in salt. After this, sufficient quantities of protein must be administered in the form of Gerson's or Hermannsdorfer's diet also low in salt content. With improving condition the patient may gradually return to a normal diet containing not too much meat or fluid and little salt, and including one or two strict vegetable days each week. In hypertension, also, a reduction of protein, salts and fats in the diet is advised. In acute nephritis, treatment must begin with a few days of fast. This combats the edema

of the tissues, the hypertension with hydremia and possible circulatory weakness, and the eclamptic as well as azotemic uremia. After the fast, treatment may be similar to that of circulatory disturbances. In chronic nephritis, a sufficient quantity of meat should be administered and rigid restriction on salt intake is not necessary. In the final stage of nephritis, protein intake must be reduced again to lower the dangerously high rest-nitrogen. The fluid intake must be low enough to prevent edema but high enough to enable the weakened kidney to secrete enough waste matter.

Splenomegalies in Childhood—Lehndorff states that swellings of the spleen in early childhood are frequent because the lymphatic tissue reacts with intense hyperplasia to all sorts of irritations. Diagnostic difficulties arise only when clinical signs of an organic disease are absent. Enlargement is not identical with disease. Gas inflation, epinephrine injection, possibly a pneumoperitoneum may be of diagnostic value. Roentgenography with a contrast medium is inadvisable. Puncture of the spleen is permitted only in case of large hard tumors if leukemic and thrombopenic conditions have been ruled out. Nonspecific splenic enlargement is found in exudative diathesis and lymphatism. Many diseases with splenic enlargement have a characteristic blood picture. Splenic tumor plays no part in polycythemia which is of the Vaquez type in children usually it is of familial occurrence with endocrine disturbances and so on, splenomegaly with simple hypochromic anemia is frequent but of little significance if occurring alone. The chlorotic anemias of nurslings are often accompanied by a moderate splenomegaly. A number of the diseases with splenomegaly are characterized by erythroblastic anemia. The spleen is very large in all forms of hemolytic anemia. Splenomegaly may be the first sign of myelosis. In lymphatic leukemia swelling of the lymph nodes is rarely lacking. Lymphogranulomatosis may involve only the spleen and the diagnosis is based on the type of fever, on leukocytosis and on the diazoreaction. Among infectious diseases splenomegaly may play an important part in the splenic form of glandular fever, infectious mononucleosis, measles, syphilis and malaria. The spleen is enlarged in splenic insufficiency with eosinophilia. Chronic thrombosis of the splenic vein is diagnosed by the variable size of the spleen and disappearance of the tumor after a hemorrhage. Gaucher's and Niemann-Pick's diseases have marked splenomegaly, and their diagnosis is made by histologic and chemical examination of material obtained by puncture.

Irradiation After Operation for Cancer of Breast.—Anschütz and Siemens point out that, in order to evaluate properly a statistical report on the results of roentgen irradiation following radical operation for cancer of the breast, the analyzed material should be carefully classified. They adopt the following classification: group 1, nonadherent tumor and no palpable lymph nodes; group 2, (a) nonadherent tumor but palpable lymph nodes which on histologic examination may already show carcinomatous invasion, (b) tumor adherent to the skin or to the pectoral fascia and palpable lymph nodes which on histologic examination show carcinomatous invasion, (c) tumor firmly adherent to the pectoral fascia skin possibly showing carcinomatous infiltration or ulceration and lymph nodes manifestly enlarged and carcinomatous; group 3, adherent tumor, enlarged supraclavicular lymph nodes and large ulcerating tumor. Group 1 comprised only 5.5 per cent of the total

number of patients. Probable enlarged lymph nodes, histologically shown not to be invaded by cancer cells, nevertheless presented a worse prognosis than small lymph nodes. Histologic differentiation did not offer reliable criteria on which to prognosticate the course of the disease. While adenocarcinoma appeared to run a more favorable course than scirrhous or medullary carcinoma, contradictory observations were frequent. All deaths were considered cancer deaths and the three and five year cures did not take into account the presence or absence of metastases or recurrence. The author has had, since 1908, 508 patients who had undergone radical operation. Of these, nine could not be found and fifteen (2.9 per cent) died shortly after the operation. Of the remaining 484 patients, 309 were submitted to irradiation following the radical operation and 175 were not so treated. Results in group 1 were good with either method, though superior with the combination method. It is noteworthy that the combined method here gave 28.8 per cent of ten year cures. In spite of good results obtained by radical operation, irradiation is not to be omitted. More striking improvement in the results was seen in groups 2 a and 2 b. The figures for the three year cure were 22.5 per cent, and for the five year cure 20 per cent higher when the combined method was used as compared with the radical operation alone. The results in groups 2 c and 3 were equally poor with either method. The principle of radiation treatment consisted of giving small doses over a long period. From six to seven exposures were given in the course of four weeks and were repeated after an interval of two months. Irradiation was kept up for two years. The tangential or flanking method of irradiating appeared to be advantageous. Local recurrences took place in 25 per cent of their material. The authors do not regard them as hopeless, for much can still be accomplished by excision and irradiation. They feel that irradiation alone as treatment for carcinoma of the breast is not justified.

Ovulation in Amenorrhea.—Heim describes two rare forms of amenorrhea. In the first patient, a girl, aged 21, menstruation had never set in, although the secondary sex characteristics had developed at the age of 15. Periodic pains in the lower part of the abdomen and tension in the breasts were absent but epistaxis set in nearly every four weeks and headaches existed almost constantly. During childhood the patient had had tuberculous processes of the maxillary sinus and of the lumbar vertebrae. The author describes the results of the examination of the internal genitalia and states that the curettage of the uterus yielded large quantities of a peculiar crumbling, whitish matter. The histologic examination of these partly caseous, partly calcareous, masses revealed only necrotic tissue without differentiable structure but with numerous calcareous inclusions. Granulation tissues or bacilli were not observed. Nevertheless, the previous history made it appear probable that these were rests of a tuberculous infection that attacked the uterine mucous membrane probably before sexual maturity was reached. After the curettage the patient commenced to menstruate regularly every four weeks, her appetite, weight and strength increased, and the headaches disappeared. This surprising result, obtained without the administration of hormonal preparations, makes it appear probable that the tuberculous infection did not destroy the entire mucous membrane but that, following removal of the obstruction, its remnants underwent the menstrual changes under the influence of the apparently intact ovarian cycle. The author thinks that conception may become possible in later years. The second case is that of a woman, aged 22, who had been healthy but

in whom menstruation did not return after a normal labor and a lactation period of twelve weeks' duration. The disorder was not a lactation amenorrhea in which there is galactorrhea and atrophy of the uterus, for the mammary secretion had ceased during the fourth month after delivery and the uterus was even larger than normal. The uterine mucous membrane was of intermenstrual thickness, without signs of proliferation and without glycogen production. Ovarian sections revealed that ovulation with rupture of the follicles had taken place several times, but cyclic changes of the endometrium and menstruation did not take place. Thus this case is an example of continuous ovulation during true secondary amenorrhea.

Exsiccation Toxicosis of New-Born Infants—Lourous relates his observations on exsiccation toxicosis in new-born infants during the hot summer months in Athens. He states that at times the incidence of the disorder was so high as to assume an epidemic character. The course of the disturbance was usually as follows. Between the third and fifth day of life the vitality of the new-born infant decreased considerably and it could hardly be wakened from a persisting somnolence. The temperature increased considerably, nearly always to 40 C (104 F) and a slightly icteric coloration was generally evident on the following day. Administration of Vichy water proved effective, and since then the author has given ordinary water several times daily as a prophylactic measure. He also advises that new-born infants be kept as cool as possible, either in thoroughly aired rooms or in a shady place outdoors, the surroundings being kept cool by means of a large ice bag. Since he has adopted these measures, exsiccation intoxication has entirely disappeared in his institution and he therefore recommends this procedure, brought to his attention through an article by Burghard to all obstetricians in hot climates.

Vaginal Surgical Method for High Tumors of Adnexa—According to Logothetopoulos, vaginal extirpation of inflammatory tumors of the adnexa was formerly done only in cases in which the tumors were located in the lowest portion of the small pelvis, because in the tumors located higher up hemostasis was too difficult with this method of approach. However, in eight cases in which a laparotomy seemed inadvisable owing to the great weakness of the patients and the extremely infectious form of the disease, he nevertheless resorted to the vaginal method, although the tumors were located above the level of the pelvic inlet. The results he obtained in these cases were so encouraging that he recommends vaginal extirpation in cases of acute inflammatory tumors of the adnexa whenever laparotomy seems too dangerous. He employs a large Schuchardt incision and, in order to save time, he ligates only the laterally located vessels, further arrest of the blood flow being obtained by application of gauze. Following extirpation of the uterus the vaginal retractor is removed, the surgeon's hand is introduced in the pelvic cavity and the tumor is removed. The author asserts that the detachment and the extraction of tumors is not essentially more difficult with this method than in the abdominal intervention.

*Familial Occurrence of Leukotrichia Annularis. A. Reyn—p. 273

*Two Cases of Polycythemia Vera Treated with Roentgen Rays. Fanny Busch—p. 279

Hernia of Esophageal Hiatus—Wagner describes the clinical and roentgen results in eleven cases of hernia of the esophageal hiatus in four men and seven women, aged from 44 to 88, revealed on examinations of the stomach made in about 3,000 patients. There were marked dyspeptic and cardiac symptoms in all cases, directly attributed to the hernia in eight.

Familial Occurrence of Leukotrichia Annularis—Reyn reports eight cases of pili annulati in four generations of one family. In the literature up to 1921 he found only twenty cases of "ringed hair" and considers it likely that because of its inconspicuous nature and the comparatively rare complications this anomaly is frequently overlooked.

Polycythemia Vera Treated with Roentgen Rays—In Busch's first case the white blood corpuscles increased to 19,000 per cubic millimeter during treatment, with simultaneous

myeloid reaction. In the second the white blood corpuscle count continued low, being at a certain time during treatment only 2,900 per cubic millimeter. The colorimetric index, however, rose to over 1 during treatment. Since the treatment ended, neither patient has had subjective symptoms.

"Selective" Thoracoplasty in Pulmonary Tuberculosis—Holst reports eighteen cases of plastic surgery of the apex and upper lobe of the lung. Two methods were used. 1. In eight cases in seven patients (one bilateral operation), resection of the four, five or six upper ribs was done, with extensive extrapleural pneumolysis. A periosteomuscular flap, formed from the soft wall freed from ribs, was placed as a cover over the loosened, collapsed lung, with tamponade over the flap. Complete collapse of the cavity resulted in seven cases and partial collapse in one, in one case an infiltration appeared in the lower lobe. 2. In ten cases, total extirpation of the two upper ribs was done, with complete division of all scalenus insertions and resection of parts of decreasing length from the third to the seventh ribs, in some cases with apicolysis in others with extrapleural operation. There was complete collapse of the cavity in seven cases and partial collapse in two, one patient died from pneumonia of the lower lobe of the lung three weeks after the operation. The author says that, if on roentgen examination, two or three weeks after operation insufficient collapse is seen, a supplementary resection of the foremost parts of the third to the sixth ribs from the axilla is done, it is important to perform the second intervention before malformation of the previously resected ribs occurs. The effect of thoracoplasty as described depends on a shortening of the transverse and of the longitudinal axis. The operation extends the indications in surgical pulmonary tuberculosis, because operative treatment of many cases of bilateral tuberculosis becomes possible and because the conservative intervention can be more readily advised than can total thoracoplasty, and it alters the indication, because in localized disorder of the apex or upper lobe exeresis should not be done before local "selective" surgery has been tried which preserves the sound lower lobe. This treatment in suitable cases in which it is successful is far less expensive than any other treatment for pulmonary tuberculosis, and surgical treatment of pulmonary tuberculosis is one of the most important methods of combating tuberculous infection.

Latent Liver Diseases—Skouge says that a positive Takata-Ara reaction in the blood serum is the expression of a considerable liver insufficiency caused by acute or chronic diffuse changes in the liver parenchyma. If the insufficiency disappears, the Takata-Ara reaction becomes negative. A continued positive reaction points to irreparable parenchymatous changes of cirrhotic kind. In several such cases, necropsy revealed pronounced cirrhotic changes of the liver although even shortly before death no clinical symptoms of a liver disturbance were evident. Determination of the coagulation band in liver disorders which is of little diagnostic value, can however, in combination with the Takata-Ara reaction contribute to clarifying the etiology of an ascites.

Skin Tuberculosis of Exogenous Origin in Adults—In the first two of the three cases reported by Rotnes, infection occurred on the chin and the upper lip, respectively, after the patients were kissed by tuberculous persons. In the third case the tuberculous ulcer on the right thumb is thought to have been an autoinfection tuberculosis, appearing as a primary complex. All three patients were women. The accompanying erythema nodosum in the second and third cases is regarded as a tuberculous allergy phenomenon.

DEAN LEWIS, M.D.
BALTIMORE

Trousseau once made this statement "To know the natural course of disease is more than one half of medicine" Today, study of the course of disease is neglected At least it is not so well known as by the earlier clinicians, who had to rely on their ability to know the course and characteristics of disease and who were less dependent than the present-day physicians on instruments of precision I have heard it said not infrequently, and I am sorry to say often with a tone of derision, that the day of saddle bag medicine is past The brain power of those who practiced saddle bag medicine was quite equal to that of physicians who practice today The physicians of that era knew disease, because of necessity they had more intimate contact with it and were in more intimate relation to it.

When the specific causes of a number of diseases were made known, medicine was revolutionized, new lanes of commerce were opened and lands, uninhabitable because of disease of unknown cause, were made tillable The present generation no longer views with wonder the automobile, no longer is amazed at the telephone and no longer regards as miraculous the radio The present generation little appreciates what a boon the recognition of the specific causes of disease has been—what aseptic surgery means

Before the advent of our modern knowledge of infection, communicable diseases devastated mankind Gibbon gives the following account of the plague in the reign of Justinian "In time its malignancy was abated and disappeared, the disease alternately languished and revived, but it was not till the end of a calamitous period of fifty-two years that mankind recovered their health and the air assumed its pure and salubrious quality No facts have been preserved to sustain an account or even a conjecture of the numbers that perished in this extraordinary mortality I only find that during these months four and at length ten thousand persons died each day at Constantinople and that many cities of the East were left vacant, and that in several districts in Italy the harvest and vintage withered on the ground The triple scourge of war, pestilence and famine afflicted the subjects of Justinian and his reign is disgraced by a visible decrease of the human species, which has never been replaced in some of the fairest countries of the globe" The historian Niebuhr, in

discussing the report on the plague in Athens by Thucydides, says "Almost all great epochs of moral degradation are connected with great epidemics The immediate effect on the people was a religious paralysis Instead of turning men to God, the scourge turned them to despair, and this not only in England but in all parts of Europe Writers of every nation describe the same dissoluteness of mourners consequent upon the epidemic. The world, scourged and devastated by an epidemic such as the plague, is not changed for the better, for afterwards the people become more avaricious and grasping, even if they have more of the world's goods than before They become more covetous and become involved in law suits, quarrels, strife and contradictions" Physical and moral deterioration go hand in hand

Nevertheless it was from such an atmosphere as this that modern medicine evolved, from a medicine that fought disease with magic and superstition to the great clinics and schools of medicine of today

Recently I looked up the definition of the word clinic. The word may be employed in a number of different ways It has been applied to one confined to a bed of sickness, for example, "Bring to us a clinic and we will instantly restore him sound and in health" The word also has an ecclesiastical usage, being applied to one who received baptism on a sickbed "Suppose the clinic or death-bed penitent to be forward in these employments" In medicine the word refers to the examination of a patient by an instructor in the presence of students, accompanied by a discussion of the nature and treatment of the case More recently the word has been applied to a group practicing medicine or to a building housing such a group Garrison has said that the basic idea of a surgical clinic as a teaching device is inherent even in a group of primitives assembled about an operating table with an eye single to learning something

DEVELOPMENT OF THE CLINIC

It is difficult to determine when medical and surgical patients were first separated from each other and distinct medical and surgical clinics formed In 1753 a clinic was established at the University Hospital in Vienna In 1776 this clinic was transferred to another hospital At this time specific mention is made of the establishment of a surgical clinic, which must not have developed to any great extent, for little or no mention is made of it in the surgical literature of that or later periods

Desault was made surgeon to the Hotel Dieu in 1785 When appointed, he requested that six beds be set aside for surgical patients So much emphasis is laid on this request that the segregation of medical and surgical patients must have been a distinct innovation

President's address before the American Medical Association at the Eighty Fourth Annual Session Milwaukee, June 13 1933

The surgical clinic had now become a distinct entity. Organization in clinical surgery was initiated. Patients were intensively studied, the clinical courses of surgical diseases were carefully followed, clinical and pathologic observations were correlated, and a postoperative follow-up system was established. This clinic became popular and at times as many as 600 visiting doctors were in attendance. During the French Revolution the clinic was closed. It died with Desault.

That separate clinics did not develop rapidly or to any great extent is indicated in a paper by Frank entitled "A Plan for a Clinical School or the Method of Teaching the Practice of Medicine in a University Hospital." This paper in which was discussed a plan for the establishment of a practical school of medicine was published in 1790. Frank in this paper gave not only a clear exposition of the basic methods of clinical instruction but also a precise statement of the relationship of the clinic to the hospital as a whole. His requirements were high for the time. He had no great consideration for his colleagues. He asked that but ten beds be reserved for clinical instruction, but he insisted on the unconditional right of the instructor to transfer any case suitable for clinical purposes to one of these beds and to remove the patient to the general ward, once the purpose of the instructor had been served. This arrangement suggests that there were not separate medical and surgical clinics as late as 1790, for the plan elaborated by Frank was merely the removal of patients from the general ward while they were being used for clinical teaching. They were returned to the general ward as soon as they had served this purpose.

A distinguished group of French surgeons appeared after the Napoleonic wars—Dupuytren, brilliant, but autocratic and severe, who probably delayed the recognition of appendicitis by almost fifty years, Lisfranc, famed for his amputation, Jobert for his work on intestinal suture, Civiale for his sound, and Denonvilliers for his complete and clear description of the fascia about the prostate. The reign of Louis Philippe probably marked the most brilliant era of French surgery. All these surgeons were highly individualistic.

A clinic in its organization often reflects to a great degree the political or governmental genius of a people. In Germany, where, during the middle and latter part of the nineteenth century, the clinic reached its highest development as a teaching and training device, anatomy, histology, physiology and pathology played important rôles in the development of those working in it. In following the career of Langenbeck, who developed the greatest clinic of the period, one must be impressed by the fact that his early investigation was far removed from general surgery. His graduating thesis was on "The Structure of the Retina." This subject was probably suggested by his uncle, who was then professor in Göttingen. This was soon followed by a paper on "The Changes in the Retina in Disease." His preparation then was widened, for he became a docent in physiology and microscopy and soon began teaching operative surgery on cadavers, giving private instruction. His training was supplemented by travels in England and France. Methods of the medical men of these two countries were closely observed. At an early age he was made professor of surgery in Kiel. The Holstein War offered him opportunities to practice war surgery. His work was so brilliant that before the

war was fairly over he was called to the chair of surgery in Berlin left vacant by the death of Dieffenbach, who fell dead when about to operate.

In 1848 when Langenbeck took over the Surgical Clinic in Berlin, there were twenty-eight surgical beds seven for first class nine for second class and twelve for charity patients. When he resigned, thirty-four years later, 189 beds were devoted to the care of surgical patients. Organization, almost military in type, was one of the outstanding features of this clinic. The chief had a graded staff, the members of which remained in the clinic over a number of years, with an opportunity to develop, work being done under supervision until responsibilities could be assumed without risk. Long preparation without outside attractions gave the men in it a scientific love of surgery which they never lost. Those in the clinic were thoroughly grounded in biology and pathology, both anatomic and experimental. The conclusions reached as the result of clinical examinations or experiments were subjected to the closest scrutiny. The rationale of joint resections, so extensively employed and popularized by Langenbeck, was based on the experimental work of Heine. He presided over the first meeting of the Deutsche Gesellschaft für Chirurgie and in his address emphasized strongly that the science of surgery must always control the art, and that animal experimentation is imperative if the science of surgery is to progress.

He had dignity without aloofness. During his entire career he published but forty-seven articles—how few, when we think of the multitude of articles published today—but deep thought and conservative originality are found on every page he wrote. He devised few operations, but his uranoplasty and methods of joint resections have stood the test of time. He was pre-eminently a developer of surgeons.

INTERDEPENDENCE OF CLINIC AND LABORATORY

Many changes were now occurring in medicine. The experimental laboratory had developed rapidly, and the problems arising in the clinic were subjected to experimental study. Virchow's ideas on investigation were thus expressed in the first number of his *Archiv*: "The ideal we shall strive to realize, so far as it is in our power, is that practical medicine shall become applied theoretical medicine and theoretical medicine shall become pathologic physiology."

"Pathologic anatomy and clinical medicine, the justness and independence of which we fully recognize, are essential to us as sources of new questions, the answering of which will fall to pathologic physiology." He continued, "Pathologic physiology takes its questions partly from pathologic anatomy, partly from practical medicine, it creates its answers partly from the bedside and thus is a part of clinical medicine, and partly from experiments on animals. The experiment is the ultimate and highest resort in pathologic anatomy." The clinic was now enlarged to provide facilities for the solution of problems which could not be solved by clinical investigation. When the field of surgery was extended after the introduction of antiseptic and aseptic procedures, the results of animal experimentation were applied to man and the knowledge of human physiology was greatly increased by the study of the effects of operation on man performed for the relief of definite lesions.

The rapid advances that were made in the knowledge of the physiology of the thyroid, hypophysis, spleen,

pancreas and other glands were primarily due to the accurate clinical investigations of symptoms associated with altered function and the changes that followed medical or surgical therapy. At times these studies did not progress rapidly and there were periods when there seemed to be little or no progress, followed by periods of intense activity, in which suddenly the problem was solved. Diabetes and the discovery of insulin is a most striking example.

It is almost fifty years since the syndrome of acromegaly was described. At first the tumor associated with this lesion was thought to be a sarcoma, and the syndrome for some time was thought to be due to destruction of the gland. Later Benda demonstrated by his mitrochondria stain that the cells composing the tumor were composed of the eosinophil cells and that the syndrome must be due to overactivity of the eosinophil cells. The relationship of altered hypophyseal function to different clinical syndromes was understood. Experimental investigation followed, and the syndromes associated with loss of secretion or altered function were definitely determined.

It is almost unbelievable that criticism should be offered of the experimental method when such rapid advances occurred. The clinic and the laboratory were interdependent. Lasegue, however, made the following statement: "But, fortunately the danger resulting from the opinion of these physiologists that they can disregard medical observation is less than one would think. They observe little and they observe badly. They explain much, or rather explain everything. They pass quickly from hypothesis to practice. But after the most adventurous excursions they all end peacefully at the same point, the point which had already been reached, and medicine proceeds undisturbed, though with caution on its onward march."

THE CLINICAL SENSE

The clinic and the laboratories are now in complete accord. Out of the gradual combination of laboratory investigation with medical practice and investigation, and teaching at the bedside came the development of our modern clinics and medical schools.

Science had taken command. The cause of many infectious diseases had been determined and preventive measures could be employed with certainty. The functions of the ductless gland were understood, and the relation of the alteration of the secretion of these to clinical syndromes was recognized and their interrelationship suspected.

The fundamentals of clinical medicine and surgery were somewhat overshadowed by the laboratory. The importance of history taking and physical examinations was gradually being displaced by the data derived from the mechanical devices, and a much greater value was placed on research than on mastery of the subject which the clinician taught. No one denies the value of research, but mastery of the subject should have an equally high rating.

It has been said of Briggs of Burnley that he knew "the face of disease." He had built up in his mind, as a consequence of teaching he had received from older practitioners and as a result of his own experiences, a number of subtle and most comprehensive pictures, each one of which represented some form of human application. For him these had a clear and definite meaning, and at the sight of any one of them Briggs would express an opinion about the prospects

of the patient showing the picture, which opinion, as a rule was justified by the event.

Medical knowledge of this kind is sometimes spoken of as "clinical sense," the implication being that it is an inborn gift possessed by but few men. This view was not held by the older physicians, for it was realized that it could be cultivated and every doctor was at pains to cultivate it himself. Assistantships and partnerships in old established practices were in consequence early sought for.

During the past year the American Medical Association has lost in the death of William Sidney Thayer one of its best friends—a past president—who exemplified in his daily practice the highest type of a clinician. He knew well the face of disease and had "the clinical sense" developed to the highest degree. I have often watched him at work and have been amazed. He had been endowed with keen senses, which he daily exercised. Thus they became more and more acute. His clinical sense was not inborn. It was developed by long years of history taking and clinical examinations made with meticulous care, the observations and end-results being correlated with the pathologic changes found at autopsy or the operating table. He possessed an accumulation of correlated experiences on which he could always call. Mechanical methods were ancillary. He would arrive as nearly as possible at a conclusion by the fundamentals of clinical medicine and ask only for those tests which he thought would contribute to an accurate diagnosis. He used the laboratory with discretion.

It is said that MacKenzie in his later days became indignant when he realized that his reputation among his colleagues was based on the very kind of work of which he had spent his life proving the fallaciousness. He had become known as the Man of the Polygraph, the Man of the Tracing and not as the Man Who had Learned to Foresee Danger. To think, the bush had been valued while the fruit was ignored. His keen and ever present sense of humor came to his rescue. He saw the comic side of it all. Once again the mechanical device, Science with a capital S, had triumphed over mind and reason.

I believe that readjustment is going on steadily and that the relation of the clinic and the laboratory is much more nearly that which is desirable than it has been in many years.

CLINICAL INSTRUCTION AND CONTROLLED EXPERIMENTATION

There can be no argument over the following statement made by the Committee on Medical Education:

Stimulating teachers who are masters of these subjects and who can inspire their students are vital features of the educational program.

There is no substitute for the master clinician in the clinical fields of instruction. It is vital that universities provide the inducements which will attract and hold clinicians of the caliber and ability which teaching in this field requires, and which the responsibilities for the care of patients in the hospital and clinic demand.

One student is attracted by one teacher, another by another. If a teacher inspires, the student observes closely and listens with enthusiasm. The subject matter is much the same, but the way it is presented, as does the relation between the student and the teacher, differs widely. The elective system, which permits students to go from one university to another, enables a student

to meet stimulating teachers whom they know because of books, articles or statements by other students. If a student selects his teacher with enthusiasm, he will probably study with enthusiasm. Enthusiasm promotes study more than programs and curriculums. Students may be idling and wasting time with one instructor or at one university and, on meeting another instructor, suddenly become enthusiastic. I have heard recently much of pedagogy. I know that one may be a great clinician and another, apparently equally equipped, never will become one. One can impart knowledge and stimulate to increased endeavor, another cannot. Pedagogy is largely a question of personality.

Controlled experimentation is the foundation stone of medical progress. Since 1871, when Philadelphia surgeons attempted to secure dogs for experimental purposes from the animal shelter which had been established by the woman's branch of the Pennsylvania Society for the Prevention of Cruelty to Animals, repeated efforts have been made to have regulative legislation passed through state legislatures. When regulations, often largely under lay control, have been made, laboratory work performed to elicit new facts or to aid in diagnosis has been seriously interfered with. Schafer has recently shown to what extremes those opposed to animal experimentation may go, and how much scientific procedures may be restricted. In Great Britain and Ireland no medical man is permitted to make a Zondek-Aschheim pregnancy test unless he has a license to practice vivisection, and then he can make such a test only in a place registered under the act. A special certificate to keep a mouse alive for a few days is required to make such a test. Hospitals debar themselves from making the observations necessary to the diagnosis of many common diseases, but even more to those diseases the rapid and efficient diagnosis of which depends on the results obtained by inoculating animals. But even when the hospital has a well equipped laboratory, experiments on living animals, whether for diagnostic purposes or not, are usually barred by the hospital authorities. Such diagnostic procedures as are employed daily cannot be made under the same roof as the patient although the treatment and prognosis depend on the data derived from such procedures. The hospital authorities fear that they may offend wealthy donors who are opposed to such procedures. The patient suffers and the most efficient care is seriously interfered with.

As far as the dog bill is concerned, Dr Grace Briscoe states the case well.

If it is wrong to use dogs in the search for knowledge, it is equally wrong to use any other of the higher animals. If it is permissible to experiment on animals for the sake of suffering humanity, then we must not shrink from applying that principle to the most domesticated of all animals—the dog—provided there is real necessity for its use. Medical women must face the issue, as they have perforce to use the results gained from animal experimentation in everyday practice. Can they in all fairness disapprove of such experimentation and, at the same time, make use of beneficial knowledge gained therefrom?

The questions most difficult of solution are those which stir the emotions. The antivivisection agitation is largely kept active and financed by women. While the propaganda is largely against a dog bill, the whole principle of animal experimentation is at stake. The members of the Woman's Auxiliary should be most active in combating this movement. Eternal vigilance

must be exercised and untiring effort maintained. It is unbelievable that those to whom we minister not infrequently believe that a Dr Jekyll is transformed into a Mr Hyde as soon as he crosses the threshold of an experimental laboratory.

The American Medical Association, aware of the defects of medical education, made an exhaustive survey and published the results in 1900. In 1904 the Council on Medical Education was formed. Later the study of the hospital situation was undertaken and the body was then called the Council on Medical Education and Hospitals. The entrance requirements to medical colleges were raised, the course lengthened, improved, pedagogic methods introduced and the entire plan of medical education reorganized—it might be justly said revolutionized.

The change that occurred is recent history. Many of the schools could not meet the requirements and were closed. At the present time there are seventy-six approved medical schools in the United States. Ten of these give only the preclinical course of two years. In addition to these approved schools there are six which are recognized as medical schools. These are located in Illinois, Massachusetts and Missouri and are not recognized by the licensing boards of other states. Their graduates may appear before licensing boards of their own state. The graduates of these six schools represent but 2 or 3 per cent of the total graduating each year.

OVERPRODUCTION OF PHYSICIANS

In spite of the reduction in the number of medical schools there has been no decrease in the number of physicians licensed. In 1918, 4,205 physicians were licensed. This small number was probably due to regulations that were set during the war. This is the smallest number appearing before licensing boards for the last fifteen years. Since 1927, when 7,269 appeared for licensure, the number has been fairly constant. In 1918 but 56.5 per cent were graduates of class A schools, while in 1931, 91.3 per cent graduated from class A schools. The quantitative change is thus seen not to be so great, the qualitative change is. There apparently is an overproduction of doctors. How such overproduction can be controlled, or whether it should be controlled, is a problem for the Council on Medical Education and Hospitals. The medical schools cannot be reduced in number to any great extent, for there may come a time when the number required to meet the need is not great enough, and medical schools do not develop rapidly. We can, however, restrict the number from foreign schools who came to us after graduation. This condition will, I believe, right itself.

At present the number of persons per physician in the United States is approximately 780. This is a lower number than in any European country. Careful studies indicate that there are in the United States 25,000 more physicians than are required. They are poorly distributed and probably will continue to be. In certain instances it might be well to consider moving people from undesirable into more happy surroundings, not for the accommodation of the prospective doctor but for the health and happiness of the people, who might, under new conditions, make surroundings and life so attractive that physicians could not resist the desire to practice among them.

The overproduction of physicians, increased specialization and improper distribution should have serious consideration at the present time.

REPORT OF THE COMMITTEE ON THE COSTS
OF MEDICAL CARE

During the past year, reports have appeared from different committees and commissions which have had to do with medical economics. The report of the Committee on the Costs of Medical Care has been discussed so often that I am sure all are familiar with the contents. I have been interested in determining what impression the report has made on lay people. They can hardly be accused of preformed or prejudiced opinion. Freehoff has analyzed the report and makes the following observations:

Therefore, the committee proposes what, as far as I can recall, is the most radical social suggestion ever made by a responsible commission, namely, that we transform our whole system of medical care. Many physicians, they say, are now connected with a hospital or with a clinic of some kind. This connection accounts for part of their activity. Every physician has in addition his private work with his patients. Now it is proposed to abolish all private work of physicians and organize all physicians permanently in these medical centers. If you want medical help you will never have your own physician, but you will be part of the services of this medical center. All work will be hospital or clinic work. As for payment, again you will not pay as you do now, namely, as you need it. There will be a voluntary insurance plan, supplemented by taxation. Every one will make a regular contribution into a social fund and every one will be entitled to go to the medical centers to receive whatever treatment he needs. All will receive the same treatment. In other words, private medicine is abolished; social medicine takes its place.

Such is the impression that a nonmedical man gets when reading the Majority Report, although we are assured by some on the committee that the bogey man of socialized medicine has scared organized medicine.

There seems to be some confusion, even among the members of the committee, as to how the complete medical service is to be given. They do not advocate a universal or common scheme of voluntary insurance. Provision of service is made through clinics in cities, whose organization and influence should radiate to the suburbs and into the country. How many groups there should be—whether separate, independent or competing, is not stated.

Included in the plan of organization is an agency in each community through which the lay and professional groups concerned in financing medical service could consult, plan and act in behalf of the best provision of medical resources which the community can afford. What constitutes the community and what the nature of the agency is indefinite.

In this report it is frequently stated that the mistakes of the European systems should be avoided. It is well known that voluntary health insurance has not been successful and that when started it has soon become compulsory. Frequently it has been stated that the mortality has not been decreased under any of these systems, and that the stay in hospitals has been doubled under them. Some interesting figures have been given concerning the panel system in England. During the period from 1921 to 1927, sickness benefit claims have risen from 41 per cent to 159 per cent, the most marked increase in claims being seen in short illnesses. In 1929, 410,903 cases were referred to the regional medical officers for the question of malingering. The prospect of an examination caused 109,661 to declare themselves off the funds, and 89,750 failed to attend for other reasons. The number actually examined was 143,898. Of these, 76,162 were found incapable of work. Thus, of the

original 410,903 five sixths were palpably frauds. This is a sad commentary on the system, which compares most unfavorably with our present system, one of the chief objects of which is to lessen the length of sickness, reduce the disabilities following injury and return the patient to economic life with an earning capacity reduced but little, if at all—a system designed to make a self-reliant, self-respecting, ambitious member of society.

THE FOUNDATION OF EFFICIENT
MEDICAL SERVICE

The family doctor or general practitioner is the foundation of any complete and efficient medical service. He knows the family and the personal history and is not infrequently the confessor and guide. Neglect of the family physician leads people to seek specialists on the slightest provocation and has encouraged men and women to enter the specialties without that long training in general medicine, pathology and hospital practice which is the foundation of successful work. We all recognize the evils that are associated with too early specialization with insufficient preparation, and still this is abetted by lack of appreciation of the family physician.

Cooperation should replace unrestricted competition. I believe that a ward should be set aside in general hospitals for general practitioners to which they might send patients requiring hospitalization. Such a ward could be properly supervised through the staff. The general practitioner would retain his patient. Work in such a ward would offer him an opportunity for continuing graduate study. I am not in favor of the university group clinics suggested by the Majority Report. The university can render, however, a distinct service by establishing diagnostic clinics, in which, for a minimum fee, a diagnostic survey can be made when required, but no patient should be admitted to such a clinic unless accompanied by a doctor or carrying a letter from a doctor. When the diagnosis is made, the patient should be returned to the doctor, with whom consultation may be held from time to time concerning the progress of the case and change in treatment. In such instances the clinic would, like the laboratory, be called on when it is needed to complete a diagnosis.

Suitable hospital construction distributed in areas according to established community needs lessens the amount of duplication in the equipment of the offices of the different physicians in the different localities and thus lessens overhead. Good roads and motor transportation make such hospitals easily accessible, even to patients at remote distances.

The duplication of expensive equipment increases the overhead, as does the elaborate and ornate construction of many of our hospitals. Many of the hospitals resemble luxurious hotels. Mencken has well said that the cost of lodging a free patient has increased at almost the same rate as lodging a pay patient, and that in most hospitals of any pretensions caring for the former the costs per diem are more than those of the average American hotel for a room, a bath and three meals.

It is suggested from time to time that doctors when paid for taking care of the sick are not apt to take a real active part in the prevention of disease. No argument need be wasted on such unfounded criticism, for health prevention movements have been initiated by practicing physicians and the record and tradition of the profession testify to their activity in the field.

Doctors welcome public health measures and, I am sure, will do everything in their power to prevent politics from entering into the field. Those in charge of public health measures should be specially trained and qualified and those practicing curative and preventive medicine should cooperate to the fullest. There should be no quarrel between the two. The greatest cause of friction will be the extension of the health service into fields on which they should not encroach.

The pregnant mother, eugenically advised, visits the prenatal clinic, and when the baby is born both pass to the welfare center, and the family is watched through the seven different ages of life. I sometimes wonder whether in trying to keep our health we shall find time to enjoy life, retain our liberty and engage in the pursuit of happiness. There is a great deal of truth in the following: "To live a full and swift, even though unhealthful life and to be speedily destroyed, is better than to live healthily and long and be bored."

We all recognize that there are defects in medicine as practiced in this country today. There will be defects in any system that is employed, because it is human nature to err and there is a lot of human nature in all of us. But, as has been stated by the Commission on Medical Education:

There are fundamental advantages in the American scheme which ought to be retained and extended. The solution of the problem is not destruction of the present system and the substitution of a paternalistic plan ill adapted to the philosophy of American life, but rather the evolution of a pattern which will embrace the desirable features of the present method and a correction of its defects.

It is obvious that there are features of finance, problems of organization and interests of the public involved in providing medical service for a community but a thoughtful examination indicates that the professional and technical features predominate. The quality interpretation and correlation of scientific knowledge are dependent on a trained personnel who know the significance of that knowledge and how to apply it.

The clinic and hospitalization have reached their present development and efficiency as the result of the successive efforts, technical skill and idealism of many generations of physicians. The same idealism and ability will settle problems as they arise. Many times their suggestions may run counter to the trends of the time. Medical statesmanship will provide the solution.

It should be remembered that organization is not a synonym of efficiency, neither is change a synonym of progress.

The Cycle of Change—At the same time standards of education and of living have been elevated so that the individual is caught between his desire for better things and his inability by his individual efforts to obtain them. In this dilemma he turns to the state or to organized industry for relief thus further sacrificing his independence of action and thought. To this, the man who values the preservation of his own individuality objects, and seeks to bring about a compromise between the interests of society and his own. As Mr. Coyle has written, "If a new culture is to come, the economic adjustment needs to be on the democratic rather than on the technocratic side. The latter calls for government of all organized society by the economic system that produces and distributes material goods. The former assumes the right of society, acting as a whole to apply certain regulatory measures to the economic system and then to devote its main interest to other things. Technocracy would abolish freedom in the interest of efficiency. Individualism in its new form would enlarge freedom of initiative at the expense of efficiency, since the efficiency of these new machines is so great that there is plenty to spare." —Harvey S. C. Oikonomia Medika, *Jalc J Biol & Med* 5 323 (March) 1933

THE POSTOPERATIVE CONTROL OF DISTENTION, NAUSEA AND VOMITING

A CLINICAL STUDY WITH REFERENCE TO THE EMPLOYMENT OF NARCOTICS, CATHARTICS, AND NASAL CATHETER SUCTION-SIPHONAGE

JOHN R. PAINE, MD
HERBERT A. CARLSON, MD
AND
OWEN H. WANGENSTEEN, MD
MINNEAPOLIS

Surgical operations are necessarily followed by pain, often requiring for its relief the administration of morphine or other narcotic drugs. In varying degree, distention, nausea and vomiting occur so regularly after abdominal procedures, particularly after operations on the upper part of the abdomen, that one tends to accept them as inevitable consequences of laparotomy. The effect of opiates on the tone and function of the gastrointestinal tract is, therefore, an important consideration in the management of patients during the postoperative period, especially on those occasions when signs of inhibitive (paralytic) ileus become prominent.

Other factors may influence the degree of distention or the incidence or severity of nausea and vomiting. Among these are cathartics, drugs acting on smooth muscle, enemas, and intubation of the upper reaches of the alimentary canal.

The work presented here divides itself into two main parts. The first is concerned with a series of postoperative cases treated with high morphine dosage, low morphine dosage, pantopon, dilaudid (dihydromorphine hydrochloride) and saline cathartics. The second deals with the postoperative use of suction applied to a Levin duodenal tube inserted through the nose into the stomach.

THE USE OF NARCOTIC DRUGS AND SALINE CATHARTICS IN THE POSTOPERATIVE PERIOD

High and Low Morphine Dosage—The constipating effect of opium and its principal alkaloid, morphine, has been recognized since their introduction into southeastern Europe shortly before the birth of Christ.

This constipating effect has usually been assumed to be due to a diminution of the tone of the intestinal musculature and force of the peristaltic activity. Statements may be found in textbooks and in current literature supporting this view of the effect of morphine on the bowel.

It is interesting to note that as early as 1865 Nasse¹ showed that morphine sulphate caused an increased frequency in the peristalsis of the intestine of frogs and rabbits. Since that time the question has been the subject of much experimentation with investigators arriving at various results. That the effect of the drug may vary with the conditions under which it is given and with the size of the dose seems probable. In 1926, Plant and Miller² studied the effects of morphine on the small intestine of dogs. Their results showed that

From the Department of Surgery, University of Minnesota Medical School.

¹ Nasse O. Zur Physiologie der Darmbewegung. *Zentralbl f. d. med. Wissenschaften* 3: 785, 1865.

² Plant O. H. and Miller G. H. Effects of Morphine and Other Opium Alkaloids on the Muscular Activity of the Alimentary Canal. *J. Pharmacol. & Exper. Therap.* 27: 361 (June) 1926.

there was a stimulation of many phases of muscular activity, including increases in tone, peristalsis and rhythmic contractions. Limited experiments on patients confirmed these results. Gruber, Greene, Drayer and Crawford³ also found that in dogs morphine caused an increase in the tone of the intestinal muscle for which effect atropine exhibited reciprocal antagonistic action. In our laboratory, it was shown⁴ that morphine uniformly enhances the tone and the peristaltic activity of the normal as well as the obstructed intestine. Observations were made on both dogs and human beings with strictly comparable results. The constipating effect of morphine is now best explained on the basis of increased tone of the sphincters and inhibition of the defecating reflex.

It was this conception of the idea of the effect of morphine on the small intestine that prompted us to determine, if we could, the effect of low and high morphine dosage on postoperative patients with respect to the severity of gas pains, the amount of nausea vomiting and distention they experienced, and the number of enemas they required. Most of our observations were directed toward patients with abdominal operations, though a fair number were made on patients with other surgical procedures for purposes of control.

Arbitrary distinctions had to be made for the 'low' and 'high' dosages. We decided to consider 'low' dosage as being doses of morphine sulphate, $\frac{1}{8}$ grain (10 mg) given not oftener than twice a day for no more than two days, and 'high' dosage as being doses of morphine sulphate, $\frac{1}{4}$ grain (10 mg) or $\frac{1}{2}$ grain (15 mg) given not less than three times a day for three days or more. Most of the patients on the 'high' dosage regimen received daily four $\frac{1}{4}$ grain (15 mg) doses for three or four days. In the patients receiving 'low' dosage in whom pain required some narcotic, codeine sulphate, 1 grain (60 mg) or $1\frac{1}{2}$ grains (90 mg) was given as sparingly as possible. Special daily records were kept on each patient. On these records were recorded the time and dosage of all morphine or other narcotic given, daily estimations of the amount of nausea, distention and vomiting, estimations of the severity of the gas pains, and a record of the bowel movements and enemas. Observations were made for five or six days after operation and in some cases for the entire period of hospitalization.

TABLE 1—High and Low Dosages

Operation	High Dosage (30 Patients)	Low Dosage (24 Patients)
Herniotomies	5	6
Cholecystectomies	11	7
Appendectomies	14	11

Thirty patients were given morphine in "high" dosage and twenty-four were given morphine in "low" dosage (table 1).

The hernias were all inguinal except one. One patient had a femoral hernia and received a low morphine dosage.

In the "high" dosage group the interval appendectomies were about twice as numerous as the appendectomies for acute appendicitis. In the "low" dosage group the division was about equal. The cholecystec-

tomies were all performed for chronic or subacute cholecystitis or cholelithiasis. The usual anesthetic in all the cases was spinal (procaine hydrochloride crystals). This was supplemented when necessary by nitrous oxide or ethylene.

In our own minds it seems that there could be no question about major surgical cases requiring narcotics. Such patients have pain which for from twenty-four to forty-eight hours is often severe enough to require morphine. In our opinion there is no justification for withholding morphine unless by its administration complicating factors are introduced or the patient's postoperative convalescence is prolonged.

TABLE 2—Effect of Morphine, Pantopon and Dilaudid on Distention Nausea Vomiting and Gas Pains

In referring to the tabulated results (table 2) it should be borne in mind that the low morphine dosage was frequently inadequate to control the pain properly, especially in the group of cholecystectomies. On the other hand, the high morphine dosage was excessive for many of the patients, notably those who had appendectomies or herniotomies. The optimum morphine requirements of the average patient lie between the extremes employed in this experimental study.

It is to be noted that distention, nausea vomiting, gas pains and constipation occurred independent of the administration of morphine. Distention of moderate or severe degree occurred with slightly greater frequency in the high morphine dosage series, but the difference is not striking and may not be significant. Nausea and vomiting were definitely increased when morphine was administered frequently and in effective doses. The nauseating effect of morphine was clearly demonstrated in certain patients who had little pain and refused further doses of morphine because it made them 'sick'. The effect of morphine on "gas pains" is difficult to evaluate because, although peristalsis and intestinal tone may apparently be increased, the patient's sensibility to pain is at the same time effectively obtunded. The number of enemas required was not found to be an accurate gauge of the constipating effect of morphine because they were usually given in a routine manner by order of the house surgeons. Furthermore, any constipating effect which might have been due to morphine (by inhibiting the defecating reflex or by increasing the intestinal tone) was obscured by the fact that practically all of the postoperative patients failed to have normal bowel movements early as an effect of the operation itself and because of the low residue diet.

No serious consequences of even excessively high morphine dosages were found in this part of our investigation. On the basis of the results obtained, we believe that morphine neither prevents nor relieves abdominal distention nor is it an important factor in its

production. No factors prejudicing the employment of adequate doses of morphine for the control of pain have been revealed by our studies.

Pantopon—Pantopium hydrochloricum is a purified mixture of the alkaloids present in opium, contains about 50 per cent morphine, is soluble in water, and is recommended in doses of from $\frac{1}{3}$ grain (20 mg) to $\frac{1}{2}$ grain (30 mg). It was introduced into therapeutics by Sahli, who with others thought that certain of the alkaloids present in opium, while relatively inert themselves as sedatives, had a marked synergistic action in increasing the analgesic effect of morphine if administered with it. Barth⁵ and Schwenter,⁶ in 1912, studied its properties and its effects on both human beings and

that it affects the bowels less and does not cause nausea as much or as often as does morphine.

It was to test certain of these claims and to note whether postoperative patients would in general be more comfortable when pantopon was substituted for morphine in a series of cases that the effects of this medication were studied. Special charts were kept on these patients as in the series concerned with morphine dosage and the same observations made. Doses of $\frac{1}{3}$ grain (20 mg) were used, though in a few cases $\frac{1}{2}$ grain (30 mg) and $\frac{1}{4}$ grain (15 mg) were substituted. Pantopon was given as required for the control of pain except in two patients who were given doses of $\frac{1}{3}$ grain (20 mg) every four hours for three days following cholecystectomies. Records were kept for from four to five days postoperatively.

Observations were made on thirty-six patients, operated on as follows: herniotomy, seven cases, cholecystectomy, eight cases, appendectomy, eight cases, miscellaneous, thirteen cases.

A study of the results in table 2 leads to the conclusion that the patients given pantopon postoperatively showed no great improvement in postoperative nausea, vomiting, distention or gas pains over patients given morphine. What differences there are are slight and could be discounted on the basis of the small number of cases observed.

What was said concerning enemas in the morphine series may be said here. Comparison is difficult since at times they were given more or less as a routine. There was, however, somewhat less constipation than when morphine was given.

From our clinical observations and impressions we cannot confirm the idea many have held, namely, that opium and pantopon exert more of a sedative and analgesic effect on patients than the amount of morphine contained in them. While the pantopon series was being run, it was the continual complaint of the nurses that the pantopon would not "hold them." This was more true of patients after a cholecystectomy than after an appendectomy or herniotomy, as might be expected.

One thing that impressed us strongly was the accumulative effect of $\frac{1}{3}$ grain (20 mg) doses of pantopon given every four hours. Two middle aged women given such doses of pantopon following a cholecystectomy over a period of three days reached such a state of narcosis that respiratory stimulants were necessary.

It did not seem to us as we saw these patients from time to time that $\frac{1}{3}$ grain (20 mg) doses of pantopon had any advantages over $\frac{1}{6}$ grain (10 mg) doses of morphine. In this connection it is interesting to note that pantopon costs approximately four times as much as morphine.

Dilaudid—Dilaudid (hydromorphone hydrochloride) is a synthetic derivative of morphine, made by the substitution of a ketoradical for an alcoholic-hydroxyl group. It was introduced into therapeutics by Gottlieb.⁸

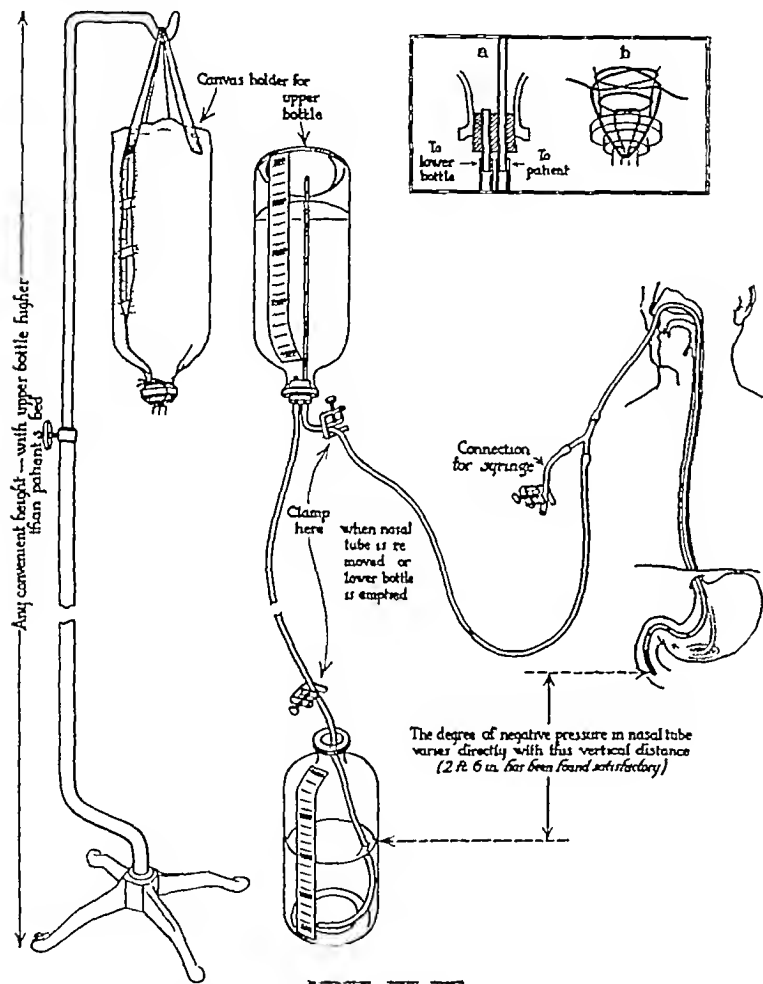

Diagram of suction apparatus used in treating postoperative distention, nausea and vomiting. Instead of the upper bottle being suspended from a standard it may be placed upright on a table or stand provided the tube leading to the lower bottle is attached to the longer glass tube instead of to the shorter one.

animals. Gruber and Robinson,⁷ in 1929, found in their experiments on dogs that pantopon increased the muscular tone of the ileum and in general had the same effects as morphine except that they were not as pronounced. Several authorities contend that pantopon is only as effective as the amount of morphine which it contains, but the drug still has its advocates who claim

in 1926, who carried out experiments with it on rabbits. His experiments tended to show that, while much more powerful than morphine in its analgesic action, tolerance was very difficult to build up.

Subsequent literature on the subject is scanty. Seeliger⁹ maintains that it has less effect on the bowels than has morphine. Dixon and Tiffeneau¹⁰ certify as to its analgesic properties. They think it resembles heroin in its actions except that, judged by withdrawal symptoms, it causes little or no euphoria. Alvarez,¹¹ on the basis of the literature and clinical use, maintained that its analgesic effect is five times that of morphine, that it is less conducive to sleep than morphine and that euphoria is much less marked. Its effects as far as nausea, vomiting and respiration are concerned are uncertain. Habituation has not been observed so far. [A personal communication indicates that Dr. Alvarez, considering these statements somewhat excessive, now withdraws largely from these views.—Ed.]

We studied the effects of this drug after operation in a series of nineteen cases to determine whether it had any qualities superior to those of morphine. The cases were divided as follows: cholecystectomy, five cases; appendectomy, seven cases; inguinal hernia, three cases; exploratory laparotomy, two cases; miscellaneous, two cases.

The experience with this drug in fifteen of the cases is given in table 1. In this small series the drug was found to be effective in controlling postoperative pain in doses of $\frac{1}{32}$ grain (2 mg.) every four hours, but it was not found to be superior to morphine in decreasing the incidence of distention, nausea, vomiting or gas pains. The only untoward effect noted was a slowing of respiration to from 10 to 12 per minute in an occasional case. A marked slowing of respiration occurred in one of our cases. A girl, aged 18 years, was operated on for acute appendicitis. The anesthetic used was an intraspinal injection of procaine hydrochloride crystals. She left the operating room in good condition and was given $\frac{1}{32}$ grain (2 mg.) of dilaudid about an hour and a half afterward for pain. Between one and two hours later her respirations fell to 10 per minute. Dilaudid was discontinued.

In two of the cases here reported, slowing of respirations to 12 or 13 per minute occurred after one or two doses of dilaudid. This was not interpreted as being an accumulative effect.

Saline Cathartics—As previously stated, varying the amount of morphine or substituting pantopon or dilaudid for morphine after operations affected constipation but little. It may logically be asked whether postoperative patients would not be more comfortable and have less nausea, vomiting, distention and gas pains if the bowels were not constipated.

Realizing that there was no generally accepted opinion on the subject, we undertook to see what effect small amounts of magnesium citrate given frequently from the first postoperative day would have. Patients were asked to drink from 350 to 700 cc. of chilled magnesium citrate solution every twenty-four hours for from four to five days after operation (350 cc. taken at once is the usual therapeutic dose). Morphine was given for pain when required. Patients complained of this treatment so bitterly that it was abandoned as not a feasible procedure. The chief complaint was the taste

After a certain quantity had been consumed, the solution seemed to make the patients nauseated. In several instances the diarrhea which it produced caused the patients so much discomfort and inconvenience that they refused to take more of it. Records were kept, however, on five patients who were prevailed on to carry the experiment through. The cases included one cholecystectomy, one appendectomy and three operations for inguinal hernia. All these patients were troubled with nausea and vomiting. In all but one case, in which an inguinal hernia had been operated on, diarrhea developed on the third or fourth day. The patient who had no diarrhea was given 450 cc. a day for the first three postoperative days. He had no bowel movements until the seventh postoperative day and experienced no distention. The other two hernia cases presented slight distention on the third and fourth postoperative days. The appendectomy and the cholecystectomy cases did not present distention.

The only deductions we could make from these five cases which were carefully observed was that, while probably not a feasible procedure, because of its nauseating effect, magnesium citrate given in large quantities immediately after operation would relieve the postoperative constipation.

THE USE OF NASAL CATHETER SUCTION SIPHONAGE IN THE POSTOPERATIVE PERIOD

Gastric lavage is probably as old as abdominal surgery, for it became a common procedure after the recurrent stomach tubes of Auerbach and Ploss were developed in 1870, and frequent reference was made to it during the last twenty years of the nineteenth century.

When Einhorn and his contemporaries developed the duodenal tube and duodenal intubation during the first decade of the twentieth century, the way was opened for further application of the principles inherent in gastric lavage. However, it was not until 1921, when Levin developed the catheter tipped nasal tube, that duodenal intubation came to play an important part in the postoperative treatment of surgical patients. In 1925, Robertson Ward¹² described the use of constant suction in conjunction with the Levin duodenal tube. The latest development has been the use of constant suction with a Levin duodenal tube in decompressing certain types of acute mechanical intestinal obstruction, as described by one of us.¹³

Physiologic Considerations—Aspiration or lavage of the stomach for continued postoperative nausea and vomiting has long been common practice among abdominal surgeons. The contributions of McIver and his associates¹⁴ on the origin of the gaseous intestinal distention after abdominal operations have adequately established swallowed air as the chief offender. The motility of the intestine being temporarily impaired, the swallowed increments of air accumulate in the intestine and distend it. Whereas the enema is an older tradition than the stomach tube, it is not surprising that

this agent is generally more highly valued and more commonly employed in the management of postoperative distention by surgeons than is its younger rival, the duodenal tube. As the chief source of postoperative distention is swallowed air, attempts at obviating its occurrence at the source would logically follow as a reasonable act. It is also immediately apparent that the continuous employment of the duodenal tube should be more effectual than its periodic use, and that a mild suction constantly applied would be more efficacious than employment of a tube as a mere siphon. The latter postulate may be found readily demonstrated in the use of a Mariotte^{14a} bottle which simulates the action of a siphon but which also permits of the collection of the aspirated fluid and gas. The details of this proof will be published elsewhere. Suffice it here to say that when the duodenal tube has been in place for some hours as a siphon, attached to a Mariotte bottle, almost invariably when suction was added, fairly large aspirations were immediately obtained. With suction, the stomach may be kept continuously empty.

The end of the catheter not uncommonly finds its way into the duodenum, in consequence, we have found it advantageous to have extra holes cut in the duodenal tube as far back as 10 inches proximal to the tip. The passage of the catheter into the intestine has been found to be a very desirable feature in that suction may be simultaneously and continuously applied to both stomach and bowel. There being no sphincters between the pyloric canal and the cecum, one may readily demonstrate to one's satisfaction on the intact dog or in the human intestine excised at necropsy, in the presence of induced distention of the intestine with either water or air, that suction applied at one end is appreciated in the same degree at the other. When a mixture of fluid and gas is present, however, the problem well known to physicists, whether dealing with rigid or elastic tubes, comes into play. In the presence of an established intestinal distention of a mixed gaseous and fluid character a slow decompression with constantly applied suction is to be anticipated even when the catheter projects beyond the pyloric sphincter. Another difficulty is the engagement of the walls of the intestine in the holes of the duodenal tube. We have employed about 75 cm of water suction, which figure we believe lies within the range of optimal values.

A turbulent intestine with active peristaltic and antiperistaltic movement, as is present in bowel obstruction may undoubtedly be decompressed by suction with greater facility than the inactive bowel of postoperative distention. Our experiences with decompression by suction in cases of acute mechanical intestinal obstruction have been previously reported.

In established intestinal distentions of a mixed fluid and gaseous nature, one favorable factor affects the issue. With the oral source for accretion of distention cut off by suction constantly applied to the stomach as well as the duodenum, the lapse of time permits of some readjustment of the relative positions of gas and fluid, facilitating their removal. Postural changes of the patient and gentle abdominal massage may also be employed in an attempt to alter the gas and fluid relationships. In addition, the intestine, like all other hollow viscera, has a great capacity for accommodating itself to various grades of distention without manifesting considerable alteration in tension. No augmenta-

tion of the distention occurring, the process of fluid absorption intervenes to simplify the problem.

Fluid Administration In the withdrawal of fluid from the stomach and upper reaches of the intestine, it is obvious that fluid replacements will have to be made to compensate for the aspirations. The oral intake of postoperative patients on suction has been limited to 2,000 cc a day, in the belief that large oral intakes will enhance the chloride loss. By quantitative determinations we have found that when 2,000 cc of oral fluid is given patients approximately 15 Gm of chloride expressed as sodium chloride will be aspirated by the duodenal tube. When 4,000 cc. of oral fluid is given, the loss is approximately 35 Gm. (In acute mechanical obstructions to be decompressed by suction, no oral intake is permitted.) Any clear liquid may be permitted, such as water, grape juice, strained orange juice, or tea. Milk or ice cream cannot be permitted as long as suction is in force, because they clot in the stomach. Fairly generous amounts of physiologic solution of sodium chloride are given subcutaneously and 5 per cent dextrose in saline solution intravenously (from 2,500 to 4,000 cc.) The best guide as to how much fluid should be given is the urine output. A daily twenty-four hour urine excretion of from 800 to 1,000 cc indicates that the fluid intake is adequate. Dechlorination of the patient need not be feared if the urine output is adequate.

Employment in Postoperative Period A detailed description of the suction apparatus by which we have maintained constant negative pressure in the upper gastro-intestinal tract together with the technic to be employed in using the Levin duodenal tube in this connection may be found elsewhere.¹⁵ We are here concerned primarily with the results obtained in treating postoperative cases by this method.

No attempt is made in postoperative cases ordinarily to intubate the duodenum with the tube. When suction is not commenced, however, until distention is established, quicker decompression may be assured if the tube can be made to enter the duodenum.

The length of time required to employ the duodenal tube varies, of course, with the individual cases. It has been found by experience, however, that in the usual case before removing the tube it is best to clamp the duodenal tube at intervals during the day and at the same time allow the patient to take oral fluids. In this way the ability of the patient to do without suction may be tested.

The usual procedure is to clamp the tube for an hour and a half out of every two hours. During this time the patient is urged to drink fluids. If under this regimen the patient experiences no discomfort over a period of from eight to twelve hours, the tube can probably be removed with reasonable assurance that he will experience no further trouble.

This procedure has been found useful in a variety of conditions in which the motility of the intestinal canal is impaired, alternate suction and feeding being done through the tube, which may be left in place for a relatively long time. Our experience with the use of nasal catheter suction siphonage in postoperative treatment up to the present time includes more than 500 cases. The impressions and conclusions that we have derived from the series of cases studied in detail and here presented have been fully borne out by our clinical observations on this larger series.

14a Edme Mariotte French physician and physicist born 1620 died 1684

15 Wangensteen, O. H. and Paine, J. R. Nasal Catheter Suction Siphonage Its Uses and the Technic of its Employment *Minnesota Med. J.* 96 (Feb) 1933

Detailed daily observations were made on thirty-eight consecutive abdominal cases, five miscellaneous cases were observed similarly as a control. The results that are presented in table 3 include only the abdominal cases.

In most instances, suction was begun as soon as the patient returned from the operating room, but in a few some hours elapsed before this was done. In most of the cases studied in this series operation was performed with spinal anesthesia. In a few instances nitrous oxide or ethylene was used as a supplementary anesthesia. The length of time suction was maintained after operation varied somewhat with the type of case. In general, it was used for three days in the herniotomies and appendectomies. Following operation on the biliary tract, suction was frequently maintained for four days and after intestinal or gastric operations for five or six days. (All patients were given morphine when required for relief from pain.)

Our experience with the employment of nasal suction in the treatment of established distention as well as its prophylactic use has indicated to us the importance of stasis in the stomach and upper intestinal canal as prob-

ably the most significant factor in the genesis of postoperative vomiting. Its value in the control of vomiting and distention of peritonitis will be made the subject of a separate report.

Charts similar to those used for the morphine series were employed on which daily observations were set down. Particular attention was paid to nausea, vomiting and distention. These cases were divided as follows: operations for hernia, seven cases, operations on the biliary tract, nine cases, operations for appendicitis, ten cases, operations on the stomach, six cases, operations on the small intestine, six cases, miscellaneous, five cases.

The study includes seven postoperative herniotomies. Five of these were inguinal hernias and two were incisional hernias. Three of the patients with inguinal hernias experienced no nausea, vomiting or distention. In one of the remaining two inguinal herniotomies there was slight distention during the first day of suction and the other patient experienced slight nausea and had an emesis of 100 cc. One of the incisional hernia patients had no distention, nausea or vomiting. The other had some nausea and vomiting during the whole period of suction.

We studied nine patients who had operations performed on the biliary system. This group includes six cholecystectomies, two explorations with drainage of

the common duct and one cholecystoduodenostomy. Distention did not occur in any of the cholecystectomies. Four patients had no nausea or vomiting. The other two had a slight amount of nausea and vomited on one or two occasions. One of the common duct cases presented a slight amount of distention but no nausea or vomiting. The other presented no distention but some nausea and vomiting. The cholecystoduodenostomy case presented nausea, vomiting and distention, all in a mild degree.

Ten postoperative appendectomies are included. Eight of this number were for acute appendicitis. The other two were interval appendectomies. Both patients were slightly nauseated and one had an emesis of 300 cc. Four of the acute cases presented no distention, nausea or vomiting, whatever. One patient was markedly distended when suction was begun, but this became progressively less while suction was continued. This patient experienced no nausea or vomiting. In the remaining three cases, distention did not occur but the patients were all nauseated and two of them had emeses of 50 and 100 cc, respectively.

The six gastric cases include two gastro-enterostomies, two gastric resections and two subtotal gastric resections. None of these patients experienced distention during the period of suction. Of the whole number, only two (following a gastro-enterostomy and a gastric resection) were nauseated and vomited.

The intestinal cases include closures of three fistulas, one sigmoid resection, one intussusception and one perforated duodenal ulcer. The patient with the perforated duodenal ulcer had no distention, nausea or vomiting. The intussusception occurred in an 18 months old baby. The infant had emesis totaling 240 cc during a two-hour period shortly after operation. The vomiting was evidently due to the nasal tube being plugged, because after it was cleaned she experienced no further trouble and had an uneventful convalescence. The patient who had a sigmoid resection had no distention but was slightly nauseated and vomited on two occasions. None of the patients having closures of fecal fistulas were distended, but two experienced both nausea and vomiting of slight extent.

By studying table 3 it is easily seen that postoperative distention was almost entirely eliminated by the employment of nasal suction. Only four patients out of thirty-eight had any distention that we could determine clinically. Only one of these had more than a very slight amount. The incidence of nausea and vomiting parallel each other closely and is greater than the incidence of distention. Many of the patients shown as having nausea and vomiting were nauseated for only a few minutes or vomited only once. Others were completely relieved when the duodenal tube was readjusted. If table 2 is compared with table 3 it can be seen how much better off these patients were as a whole than patients not treated with nasal catheter suction-siphonage.

The results following gastric operations should be mentioned in particular. More consistent comfort and benefit from the procedure seems to be derived in these cases than in any other type. One of our patients had a partial gastric resection for a recurrent chronic peptic ulcer. He had had elsewhere three previous operations on the stomach without nasal suction and was in a good position to judge of its merits. On the third postoperative day he was asked what he thought of the nasal tube. His reply was, "I never knew any one could have an operation on his stomach and be so comfortable."

As previously stated the Levin duodenal tubes, which we employ at the present time in treating postoperative patients with nasal catheter suction siphonage, have the perforations at the tip continued back some 9 or 10 inches. The tubes used on some of the patients in the earlier part of this series were not so cut, and we thought that this might account for the occurrence of some of the nausea, vomiting and distention, as suction was not simultaneously exerted on the stomach and the intestine.

In order to confirm this impression, eleven additional postoperative cases were treated with duodenal tubes in which the perforations were continued back from the tip for 9 or 10 inches. These eleven cases included four cholecystectomies, three appendectomies, one nephrectomy, one repair of an incisional hernia, one colostomy and one lysis of intestinal adhesions followed by the establishment of pneumoperitoneum.

These patients were all operated on under spinal anesthesia (procaine hydrochloride crystals). In four cases the spinal anesthesia was reinforced by ethylene-ether.

Suction was started immediately after operation or as soon as the patient regained consciousness and was discontinued in most instances after forty-eight hours. For the first twenty-four hours constant suction was maintained, but during the second twenty-four hours it was shut off for an hour and a half out of each two hours. The patients were given 2,000 cc. of clear strained oral fluid each day.

The results were as follows. None of eleven patients exhibited any distention whatever that could be determined clinically during their convalescence. Three of the patients were either nauseated or vomited. A cholecystectomy was performed on a man, aged 43, for chronic cholecystitis. During his second postoperative day he experienced some nausea when the tube was clamped. He experienced no trouble, however, during the rest of his convalescence. An incisional hernia following a cholecystectomy was repaired in a woman, aged 55. She was distressed by some nausea during the first forty-eight hours after operation and had one emesis of 150 cc. Except for this, her convalescence was uneventful. A woman, aged 33, suffering from chronic partial intestinal obstruction had an intestinal lysis and pneumoperitoneum performed. Suction was continued in this case for four days. During this period the patient became nauseated four times and had three emeses, which totaled 600 cc.

The results in these eleven patients would seem to indicate that the employment of duodenal tubes with multiple perforations will decrease the incidence of nausea and vomiting but not entirely eliminate them.

Constipation. Postoperative constipation is not affected to any appreciable degree by nasal suction. There are also several factors operative in its causation which are not influenced by decompression of the upper gastro-intestinal tract. Neither can suction be said to be an effective treatment or prophylactic for "gas pains." They still occurred and, though their incidence may be somewhat less, "gas pains" cannot be wholly controlled by suction.

Enemas are rarely needed in the postoperative period when suction is used. Previously, we ordered a soap-suds or Noble's enema on the third postoperative day as a routine and frequently repeated this on subsequent days, until the bowels were moving normally. By using suction, the patient suffers little or no distress, and

enemas are given only if the patient fails to have a bowel movement after five or six days.

Amount of Gas and Fluid Aspirated. In this connection it is interesting to note how much gas is removed from the gastro-intestinal tract by the duodenal tube. The source of this gas is largely swallowed air and is naturally subject to a good deal of variation. Following appendectomy and herniotomy, about 2,000 cc. of gas is aspirated daily. Following operations on the biliary tract, some 3,000 cc. is removed, and after gastric operations the daily gaseous recovery is about 3,500 cc. These figures are averages for the cases observed.

The fluid aspirated by the duodenal tube corresponds in quantity rather closely to the amount of oral fluid given and varies with the degree of intestinal paresis present. The fluid drainage following appendectomy and herniotomy is about 1,800 cc. a day, following operations on the biliary tract it is about 1,500 cc., and following gastric operations, about 3,000 cc. These figures hold only for oral intakes of no more than 2,000 cc. a day.

Indications for Use of Suction. The question that logically arises is: What are the indications for using nasal catheter suction-siphonage postoperatively? Several factors must be considered. One is the discomfort caused the patient by the nasal tube. In general, this is slight. Another is that many patients undergo operations within the abdomen and experience little postoperative discomfort that would be relieved by suction. Another point to be remembered is that while nausea and vomiting can usually be relieved by suction after they occur, distention of the parietic intestine is more easily prevented than relieved after it becomes established.

At the Minnesota General Hospital we use the method quite as a routine after all operations on the biliary tract, the stomach and the intestine. After simple appendectomies and herniotomies it is used only if during the postoperative period the patient suffers unduly from distention, nausea or vomiting. It is frequently employed following kidney operations and appears to be an effectual agent in the treatment of intestinal distention of many diverse origins. In the reflex ileus accompanying many infections, nasal suction is of value in controlling intestinal distention. In instances of diffuse peritonitis of appendiceal origin, we employ the conservative nonoperative treatment and find that nasal suction is of value in preventing or reducing established distention. In fractures of the pelvis followed by intestinal distention and in injuries of the spinal column associated with injury of the spinal cord and attendant intestinal distention, nasal suction has proved of great value. Many instances of simple mechanical obstruction of the small intestine, especially of the adhesive type, whether of remote or recent origin, can be decompressed by nasal suction alone without operation.

CONCLUSIONS

1 Morphine neither prevents nor relieves abdominal distention, nor is it an important factor in its production.

2 No factors prejudicing the employment of adequate doses of morphine for the control of pain have been revealed by our studies.

3 The optimum dosage of morphine for postoperative patients is determined by the amount necessary to relieve pain adequately and lies probably somewhere between the dosages used in our two series.

4 Pantopon used postoperatively shows no marked advantages over morphine.

5 Dilaudid, while effective in relieving pain, shows no marked advantages over morphine if used postoperatively. It occasionally depresses respiration markedly.

6 Saline cathartics (magnesium citrate) used immediately after operation are effective in relieving constipation but are not recommended because of their other disturbing effects.

7 Nasal catheter suction-siphonage used postoperatively is an effective method of increasing the patient's comfort and reducing the postoperative incidence of distention, nausea and vomiting. Its use also practically precludes the necessity of administering enemas in the early postoperative period.

8 Nasal catheter suction-siphonage is recommended for routine use after operations on the biliary tract and the stomach and after plastic and anastomotic types of operations on the intestine. It may also be employed with benefit in instances of established intestinal distention of an inhibitive (paralytic) character.

AGRANULOCYTIC ANGINA

TREATMENT BY THE USE OF PARENTERAL AND ORAL LIVER EXTRACT: PRELIMINARY REPORT

FRANCIS L. FORAN, MD

HOWARD M. SHEAFF, MD

AND

RALPH W. TRIMMER, MD

Assistant Clinical Professors of Medicine, Rush Medical College
CHICAGO

The syndrome described by Schultz¹ under the term of agranulocytic angina, and more recently known as malignant neutropenia² or pernicious leukopenia,³ still presents a grave, acute medical emergency for which no highly satisfactory treatment has yet been finally demonstrated.

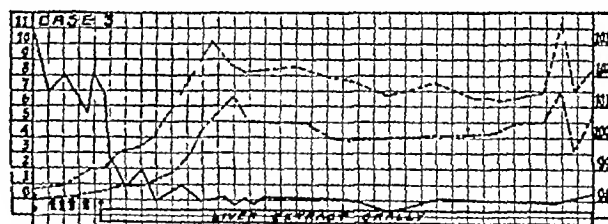

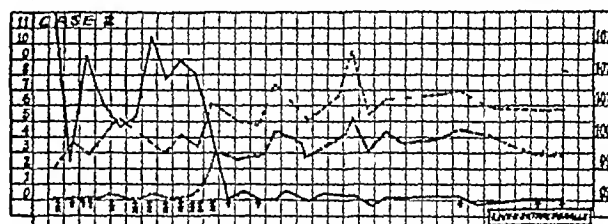

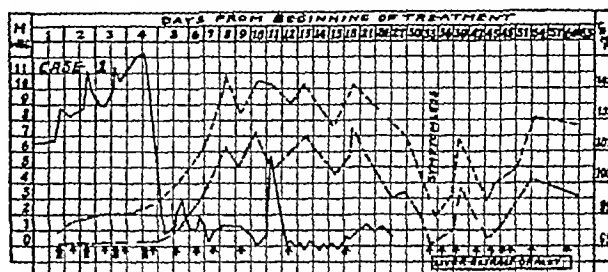

Doan² gives the mortality of the untreated cases at 90 plus per cent, of those treated by blood transfusions, at 64 per cent, and of those treated by roentgen irradiation, at 53 per cent. Jackson and his associates⁴ report a corrected mortality rate of 30 per cent for the pentose nucleotides, in which deaths during the first seventy-two hours of treatment and cases otherwise inadequately treated are excluded. One of us⁵ reported a case in which the treatment of this disease by the intravenous administration of liver extract was followed by recovery. We are now engaged in further study of this therapy and present these five cases as a preliminary report.

A leukopoiesis following the parenteral injection of liver extract has been noted by Murphy,⁶ Connery and

Goldwater,⁷ and Conner⁸ in their studies on pernicious anemia. These observations, together with the widely current view⁹ that malignant neutropenia is primarily a disease characterized by a defective function of bone marrow, furnish the logical basis for the use of liver extract in treatment.

METHOD OF TREATMENT

The parenteral extracts used were commercial preparations of the fraction G of Cohn. Our usual procedure was to inject the equivalent of 100 Gm of liver into the vein or muscle every eight to twelve hours until a definite rise in the total white and the granulocyte count or a marked clinical improvement occurred. We preferred the intravenous route for the more acute stages. When thus used, the extract was usually diluted to a volume of 20 cc with distilled water and at

Solid line temperature, broken line leukocytes, dot-dash line granulocytes, plain arrow intramuscular liver extract, barred arrow intravenous liver extract.

least five minutes was consumed in the injection. In the less acute stages, the intramuscular or oral route was used. After recovery, a dosage of liver adequate to maintain a normal leukocyte level was continued.

REPORT OF CASES

CASE 1—S. R., a woman, aged 44, whose initial attack has been reported⁵ was examined in December, 1931, at which time the red blood cells numbered 4,350,000, the white blood cells, 2,200, with polymorphonuclears 14 per cent. Recovery followed the intravenous administration of liver extract. There was a recurrence of the condition in July, 1932, when the red

blood cells numbered 4 540,000 the white blood cells 900, there were no granulocytes. The course and treatment are indicated on the accompanying chart. During a period of seventeen months there have been observed two typical attacks of agranulocytic angina, one nearly complete and several lesser granulopenic stages without symptoms and two such stages with inflamed hemorrhoids. April 18, 1933 the white blood cell count was 8 450 with polymorphonuclears, 63 per cent. The patient is now clinically well.

CASE 2—E. S., a woman aged 39 had a symptomless leukopenia (4 550) in March, 1932. In January, 1933 following a tooth extraction an oral slough developed. At this time the red blood count was 4 160 000, white blood count 2 300, polymorphonuclears 8 per cent. The course and treatment are shown in the chart. The patient recovered. April 21 the white blood count was 6 450, with polymorphonuclears 58 per cent.

CASE 3—H. S. J., a woman aged 43 had a white blood count of 5 300 casually noted in January, 1931. In September, 1932 there was exhaustion and gingival ulcerations appeared. The red blood count was 4 000 000, the white blood count, 850 and no granulocytes. The course and treatment are charted. There was a mild recurrence in December 1932 at which time the white blood cells numbered 3 100, polymorphonuclears were 30 per cent. The patient recovered. April 15 1933 the white blood count was 8 200 with polymorphonuclears 84 per cent.

CASE 4¹⁰—J. D. K., a woman aged 56 entered the hospital Feb. 2 1933 in coma with ulcerations in the mouth and throat. This was her first attack. The red blood cells numbered 3,410 000 white blood cells 1 400, granulocytes were 17 per cent. The equivalent of 1 500 Gm of liver was given parenterally. February 3 to 12 the equivalent of from 200 to 300 Gm daily by mouth. February 4 to 27 February 2 and 15 500 cc of blood was transfused. The patient recovered. February 22, the white blood count was 5,200 granulocytes were 47 per cent. Second attack. The patient continued to be well for one month, taking oral liver extract daily. March 28 lobar pneumonia set in at which time the white blood count was 650. The patient died March 30. Parenteral liver was not given in the terminal illness.

CASE 5¹¹—G. S. a woman aged 38 entered the hospital April 12, two days after onset of the illness with pharyngeal ulcerations and a temperature of 100 F. The red blood count was 3 800 000, white blood count 2,350 there were no granulocytes. The equivalent of 2 000 Gm. of liver was given parenterally, April 12 to 18 and the equivalent of 300 Gm daily by mouth, April 18 to the present. The patient was discharged April 23. April 21 the white blood count was 7 000 with polymorphonuclears, 54 per cent.

COMMENT

Remissions of the granulopenia followed the treatment by liver extract in all five cases. One patient died in a recurrence of granulopenia during an attack of lobar pneumonia, the other four remain clinically and hematologically well.

The resemblance of the leukocytic increase to the reticulocyte rise in pernicious anemia was very striking in four cases. A more sluggish rise occurred in case 4, this was the most toxic case of the series.

Obviously, the results of this brief series are not to be considered as adequate evidence of a specific effect of liver on the granulopenia of agranulocytic angina. We merely propose the further study of liver extract as a rational therapeutic experiment in this disease, which has such an obscure etiology and such a high mortality, and the treatment of which is so notoriously unsatisfactory.

TUBERCULOUS MESARTERITIS WITH ANEURYSM OF THE FEMORAL ARTERY

REPORT OF A CASE

ELDEN C. BAUMGARTEN, M.D.

AND

MEYER O. CANTOR, M.D.

DETROIT

Tuberculous arteritis as the result of the direct extension from a tuberculous process to the small arteries in a body organ is not of sufficient clinical importance to merit reporting. These lesions are considered an integral part of the primary disease, whether it is tuberculosis of the lung, kidney or any other part of the body. Such lesions do not give rise to signs or symptoms per se, with the result that a diagnosis can not be made except by examination of the microscopic sections. An arteritis in these small visceral vessels in an organ the seat of tuberculosis is of no clinical importance, moreover, as such lesions do not alter the course of the primary disease.

The tuberculous invasion of an artery of moderate or large size, however, initiates a train of events that leads to the formation of distinct disease entities, which are often diagnosed clinically and which overshadow the primary lesion as a cause of death. Tuberculous caseating mediastinal or mesenteric glands that are the primary source of the disease may exist for years without causing marked symptoms, but, should these caseating glands by direct extension cause an involvement of the wall of the aorta, there is initiated a train of events that in a variable length of time terminates in the death of the patient.

The formation of aneurysms as a result of the bacterial invasion of the wall of an artery either by direct extension or as a result of a mycotic embolism has been known for many years. The first record of the production of an aneurysm as a result of the invasion of the vessel wall by the tubercle bacillus was in 1895, when Kamen¹ described the case of a soldier, aged 24, who had a chronic pulmonary tuberculosis and an acute military tuberculosis, the former caused an aneurysm of the ascending portion of the aorta just above the aortic cusps, by direct extension from the caseating mediastinal glands.

Since this first report by Kamen, twenty cases of aneurysm of medium sized and large arteries, the result of tuberculous invasion of the vessel wall, have been reported in the literature. Of these twenty cases however in only four was this tuberculous arteritis due wholly to the hematogenous dissemination of bacilli with the lodgment of tubercle bacilli in the media of the vessel wall, having passed through the vasa vasorum. The primary source of the tuberculous process was definitely known in all four cases. The embolic nature of the process was proved by the tuberculous involvement of the vessel wall alone with no vestige of any tuberculous process in the circumjacent tissue of the vessel involved.

PREVIOUS CASES REPORTED

The first of these cases reported was that of Pel of Amsterdam, as recorded by Lenoble² in 1922. Pel

¹⁰ For the opportunity to observe and report this case we are indebted to Dr. T. S. F. Johnson of Joliet, Ill.

¹¹ For the privilege of reporting this case we are indebted to Dr. Frank B. Kelly of Chicago.

¹ Kamen, L. Aortenruptur auf tuberkulöser Grundlage. Beitr. z. path. Anat. u. z. allg. Path. 17: 416, 1895.
² Lenoble, E. Arch. d. mal. du cœur 15: 677 (Oct.) 1922, quoted by Malcolm.

reported the case of a woman, aged 20, who died of an aneurysm of the superior mesenteric and femoral arteries, undoubtedly of tuberculous origin. The autopsy showed tubercles to be present on the mitral valve. Pel considered that the vascular lesions in this case were due to tuberculous emboli from the mitral valve.

The second case was that of Tozer.³ This was a tuberculous aneurysm of the abdominal aorta which ruptured into the duodenum. In the media, which was very much thinned out, the elastic tissue was replaced by fibrous tissue filled with lymphocytes. The intima showed tuberculous granulations with numerous giant cells.

The third case was that of Brockman⁴ in 1926. This was an aneurysm of the femoral artery in a boy, aged 14. Brockman considered his case to be one in which the tubercle bacilli were carried from a Pott's disease by means of the vasa vasorum into the media of the femoral artery, producing there the characteristic tuberculous lesion resulting in an aneurysm.

The fourth case was that of Malcolm⁵ in 1928. A man, aged 72, had a femoral aneurysm that ruptured. The primary source of the tuberculous arteritis was a milary tuberculosis of the lung. Malcolm was able to demonstrate acid-fast bacilli in the media. These acid-fast bacilli conformed to the size, shape and staining reactions of the tubercle bacilli, which he considered them to be. In addition to these bacilli there was extensive necrosis of all coats of the artery with numerous giant cells and lymphocytes. He considered the portal of entry to the arterial wall as being the vasa vasorum.

PATHOLOGY

The case we are reporting falls in the small group of four cases mentioned, in that there was definitely an involvement of the blood vessel walls, especially the media, solely as a result of the spread of tubercle bacilli through the vasa vasorum into the media, in which the tuberculous process was set up and caseation necrosis occurred, so weakening the vessel wall as to result in an aneurysm. It is recognized at the present time that the necessary antecedent of aneurysm formation is injury to the media of the vessel. Adventitia and intima lesions in themselves do not result in aneurysms. An atheromatous plaque in the intima in itself will not lead to an aneurysm, but if the pressure of the blood in the vessel is sufficient to push this plaque toward the media, compressing and weakening the media by breaking the elastic fibers holding the muscle fibers of the media together, then the stage is set for the appearance of an aneurysm at that point of medial weakness.

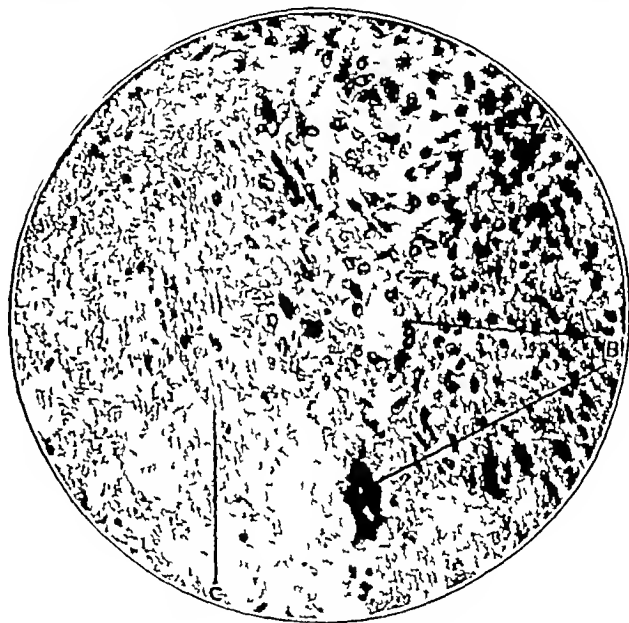

Our case differs from the four previously mentioned in that the primary source of the tuberculosis is unknown. It is possible that we have here a primary tuberculous mesarteritis. Time alone will reveal the primary focus of tuberculosis, if it is present.

REPORT OF CASE

History—A B, a white man, aged 53, seen at the Evangelical Deaconess Hospital, Nov. 20, 1929, complained of a painful swelling on the inner surface of the left leg above the knee, of three weeks' duration. The onset of symptoms occurred two

years previously. At that time there was pain in this region but no swelling. The pain was continuous. It was of two weeks' duration at that time. There was no history of trauma. The pain disappeared spontaneously and he remained perfectly well until three weeks before admission. At this time, in addition to the severe pain that occurred at the same site as two years before, a swelling made its appearance on the inner surface of the left leg above the knee. This swelling had slowly but progressively increased in size. He did not know whether there had been any fever during this time. At the time, the pain radiated down the left leg to the knee and to the calf of the leg.

Examination—The patient was well developed and apparently not acutely ill. He walked unsupported, but with a left sided limp. There was a large swelling on the internal surface of the left thigh at the junction of the middle and lower thirds. The swelling was globular in form and measured about 7.5 cm in diameter. It was firm, with a suggestion of fluctuation at its lower border. The tumescence was not movable but did not seem attached to the femur. There was no bony tenderness along the course of the femur. The temperature on admission was 98.6 F. The white blood count was 8,700. A roentgeno-

Section of femoral artery. A lymphocytic infiltration. B giant cells. C caseating tubercle.

gram of the left femur showed a periostitis with what appeared to be a small area of osteomyelitis of the lower third of the femur. The roentgen diagnosis was osteomyelitis.

Operation—November 21, under ethylene-gas anesthesia and with a high tourniquet, a slightly curved incision was made over the upper part of the tumor. The muscles were retracted, exposing a globular tumor that had a fluctuant feel. This mass was not attached to the bone. It seemed to pulsate and was compressible, suggestive of an arterial aneurysm. A needle was introduced and liquid blood withdrawn. The tumor was opened. It was found to contain a large amount of liquid and clotted blood. This was removed. Many of the clots showed beginning organization, indicating that this false aneurysm or hematoma had been formed some time prior to the time of operation. The deepest part of the cavity appeared to be lined with endothelium, but this did not cover more than one fourth of the inner surface of the sac. On releasing the tourniquet, there was active arterial hemorrhage from two openings on the bottom of this sac. These openings were closed by catgut sutures, effectively controlling all bleeding. The wound was then packed with gauze and temporarily closed with silkworm gut sutures. The patient was in fair condition. We felt that this was an arterial aneurysm which had undergone spontaneous rupture with extensive hemorrhage into the surrounding tissue. We were not able to identify the vessel definitely but because

³ Tozer, E. A. Arch. d. mal du cœur 8:312 1915 quoted by Malcolm.⁵

⁴ Brockman, E. P. Aneurysm of the Femoral Artery in a Patient with Pott's Disease of the Spine. Brit. J. Surg. 14:671 (April) 1926.

⁵ Malcolm, R. B. Aneurysm Due to Tuberculosis with the Report of a Case of Tuberculous Aneurysm of the Right Femoral Artery. Canad. M. A. J. 19:33 (July) 1928.

of its rather small size and location believed it to be one of the smaller branches of the femoral rather than the femoral artery itself

Postoperative Observations—There was no bleeding after the operation

November 26 the packing was removed. There was no bleeding. A soft rubber drain was inserted and a pressure dressing applied to obliterate the cavity left by the packing

November 29, the soft rubber drain was removed. The wound was healing nicely. There was a small amount of purulent drainage. The silkworm gut sutures were removed

December 5, the patient noted the sudden appearance of fresh blood coming from the dressings. This very shortly became a brisk hemorrhage. He was taken to the operating room immediately. The wound was opened under gas anesthesia. It was found that the large cavity previously noticed was practically all filled in, leaving only a small sinus which barely admitted the forefinger. This sinus was tightly packed with one-half inch iodoform gauze and a pressure bandage applied. The patient's leg was elevated and put in a splint

December 11, the red blood count was 1,300,000, hemoglobin, 30 per cent. He had another moderate hemorrhage. We advised transfusion and amputation of the leg

December 12, he was given a transfusion of 500 cc of citrated blood by the indirect method

December 16 he was taken to the operating room, and under ethylene-gas anesthesia the left leg was amputated at the junction of the upper and middle thirds, under tourniquet, by the long anterior and short posterior flap method. His convalescence was uneventful. The wound healed well

December 30, the patient was discharged

At the present time, three years after the operation, the patient is ambulatory without any marked disability

Pathologic Changes—Grossly, the examination of the femoral artery revealed a rupture of an aneurysm at the middle third of the leg, producing a large hematoma in the tissue of the thigh. There was organization of many of the large blood clots. There was no gross evidence of disease about the artery

Microscopically, sections taken from the femoral artery at the point of rupture revealed numerous caseating tubercles with numerous giant cells. The nuclei of the giant cells were arranged like a wreath at the periphery of the cells. There was a marked lymphocytic infiltration. The several coats of the artery had become distorted by the tuberculous process. The most marked changes, however, were seen in the media of the vessel. It was here that the caseating tubercles and giant cells were particularly abundant. An examination of the photomicrograph taken of the section from the femoral artery shows exceptionally well the characteristic tuberculous lesions. The large caseating tubercle in the media is obvious. There are two giant cells also seen very well in the photomicrograph. There was an area of fibrosis in the region between the caseating tubercles and the lumen of the vessel. At this point there was a break in the continuity of the internal elastic lamina. No tubercle bacilli were found, as a Ziehl-Neelsen stain was not done

COMMENT

An interesting feature of this case is the observation that the aneurysmal dilatation caused an irritation of the periosteum of the femur with the result that a diagnosis of osteomyelitis was made by the roentgenologist because of the resulting periostitis

The first clinical sign detectable was the swelling of the thigh. At this time the aneurysm had already ruptured, with the formation of a false aneurysm or hematoma. This was the mass found at operation, and it was for this reason that the diagnosis was not made preoperatively as the thrill, bruit and murmur characterizing aneurysms was not noted. The almost complete localization of the tuberculous process to the media is very significant. That this case is an example of tuberculous arteritis as a result of the spread of tubercle bacilli through the vasa vasorum is unquestionably shown by the localization of the process pri-

marily to the media and the complete absence of any tuberculous process in the tissue sectioned about the artery. There is a question in this case as to the possibility of this being a primary tuberculous mesarteritis. However, that is a question which time alone will settle. We did not stain for acid-fast bacilli, as the microscopic report was wholly unexpected. The microscopic report was done by Dr Phinn Morse

In the case reports of Haythorn⁶ and in that of Malcolm, tubercle bacilli were actually demonstrated in the sections in the media of the vessel wall

SUMMARY

1 Tuberculous arteritis as an etiologic factor in the production of aneurysm is relatively rare, only twenty cases being found in the literature

2 The case here reported is the fifth in which the tuberculous arteritis was the result of transmission of tubercle bacilli through the vasa vasorum into the media of the vessel wall

3 The predominant tuberculous lesion was found in the media

4 Of the five cases of tuberculous arteritis as a result of transmission through the vasa vasorum, four of the cases involved the femoral artery

5 The primary focus of the tuberculosis has not yet been found in our patient. For this reason, a diagnosis of primary tuberculous mesarteritis is justified at this time

AMYL NITRITE AND CYANIDE POISONING

K. K. CHEN, PH D, MD

CHARLES L. ROSE, BS

AND

G. H. A. CLOWES, PH D

INDIANAPOLIS

Methylene blue (methylthionine chloride U S P) has been shown by Sahlin,¹ Eddy,² Brooks,³ Hug⁴ and Hanzlik⁵ to antagonize the action of cyanide in animals, and recently it has been successfully used by Geiger⁶ in the treatment of cyanide poisoning in a man. Hug⁴ has demonstrated that sodium nitrite is a better antidote than methylene blue in dogs. He⁷ and Wendel,⁸ working independently, have offered a new view concerning the antagonism

We have investigated both methylene blue and amyl nitrite in cyanide intoxication and have found the latter to be more efficient than the former. The differences in the results appear to be so decisive as to merit a presentation to those who are interested in the subject. It should be understood that we make no claims to originality in this study but merely announce our con-

firmation of Hug's and Wendel's work with a practical suggestion

Sodium cyanide-Merck, methylene blue-Merck, both reagent quality, and amyl nitrite-Lilly dispensed as pearls, each containing 0.3 cc, were used in our experiments. It was found that the minimal lethal dose of sodium cyanide in mice by subcutaneous injection varied from 8 to 14 mg per kilogram. In rabbits the minimal lethal dose was determined to be 2.2 mg and in dogs 6 mg per kilogram. Methylene blue given intravenously, in order to be effective in mice and rabbits, must be administered within a short time, ranging from five minutes before to one to two minutes after the subcutaneous injection of sodium cyanide. The maximal amount of the cyanide successively antagonized by methylene blue was twice the minimal lethal dose. In dogs, similar results were obtained when the dye, either in a single dose or by repeated injections, was introduced directly into the blood stream, as shown in the table. No animal was protected by methylene blue medication against three minimal lethal doses of the cyanide.

Signs that indicate immediate administration of amyl nitrite are rapid pulse, difficult breathing, muscular rigidity, sluggishness or absence of corneal reflex, and convulsions. In several dogs, we commenced to give amyl nitrite every three to five minutes approximately five to seven minutes following the injection of fatal doses of cyanide. This prevented the occurrence or at least reduced the number and severity of convulsions. Each inhalation lasted from fourteen to thirty-one seconds. During convulsions, however, it was sometimes prolonged to more than a minute. While the assumption of the formation of cyanmethemoglobin by Hug⁴ and Wendel⁵ for the mechanism of detoxication has a sound foundation, Hanzlik's suggestion made in discussing Wendel's paper at the Cincinnati meeting of the Federation of American Societies for Experimental Biology, that a cyanide antidote is of great value in the relief of convulsions and tremors, should be given due consideration. In our experiments on dogs, the preventive and prophylactic action of amyl nitrite against muscular rigidity and convulsions was very apparent. The frequency of amyl nitrite inhalation should be

Comparison of the Antidotal Effect of Amyl Nitrite and Methylene Blue in Dogs

Date of Experiment	Dog Number	Sex*	Body Weight, Kg	Sodium Cyanide (Subcutaneous)			Antidotal Medication		Ultimate Result

By the inhalation of amyl nitrite, dogs can tolerate four minimal lethal doses of sodium cyanide, as shown in the table. One of the two animals that received four and a half minimal lethal doses also completely recovered. Those that died from larger doses of the cyanide seemed to have a tendency to survive longer when treated with amyl nitrite. Experimentally, the efficiency of this drug in antidoting cyanide poisoning is thus at least twice that of methylene blue, and it possesses the added advantage of being readily administered by the respiratory route.

With these laboratory data available, we believe the clinician is now justified in trying amyl nitrite inhalation in cyanide poisoning. The few observations made on animals, especially dogs, may possibly serve as useful guides in practice. The inhalation of amyl nitrite invariably changes the intoxication of sodium cyanide from a rapid to a protracted course. Continuous observation of the subject is of the utmost importance

reduced to once every thirty minutes and finally every two to five hours as the pulse and respiratory rates approach normal. A temporary improvement of the subject's condition after initial medication does not insure ultimate recovery or indicate discontinuance of observation. One of our dogs (23 in the table) when left alone died, after having been watched for twelve hours.

It may be suggested that a rational procedure in managing a case of cyanide poisoning based on animal experiments might consist of (1) immediate administration of amyl nitrite for from fifteen to thirty seconds, to be repeated every three to five minutes if the patient is unconscious and rigid, (2) gastric lavage at once if the poison is taken by mouth—preferably done by another physician for division of labor, (3) artificial respiration by hands in case of gasping while the administration of amyl nitrite is continued, (4) frequent counting of pulse and respiratory rates, and (5)

continuous observation of the patient for at least the first twenty-four hours. During convulsions, the inhalation of amyl nitrite may be prolonged to a minute or slightly longer. When respiration and heart rates show little or no abnormality, the administration of amyl nitrite should be reduced to once every several hours. To combat severe headaches that may occur, an analgesic with no depressive action on respiration may be employed.

Our study on other nitrites is in progress but a priori they offer disadvantages: the decomposition of an aqueous solution such as that of sodium nitrite, the explosive nature of organic nitrates, the necessity of repeated intravenous injections, and the risk of introducing into the circulation an overdose of a fixed drug. Unless a member of the same group proves to have a higher therapeutic efficiency, it seems better to use amyl nitrite which is rapid in action, easy to administer by inhalation, and readily available.

CEREBELLAR HERNIATION INTO FORAMEN MAGNUM

A. E. BENNETT, M.D.

OMAHA

Any one who has performed a large number of cranial necropsies has been impressed with the frequent finding of a pressure cone of the cerebellum herniated into the foramen magnum in states of increased intracranial pressure. Every neurosurgeon likewise fears this condition and frequently finds the cerebellum wedged into the foramen magnum and extending down into the cervical subarachnoid space. The surgeon, as a matter of routine, taps the ventricle before exploration of the posterior fossa in order to prevent medullary paralysis from a jamming herniation.

Despite these common observations, very little information is available as to the clinical frequency of the complication or as to the symptoms and signs of cerebellar herniation. The literature is almost bare of clinical descriptions of this important complication of increased acute or chronic cerebral pressure syndromes. Only a few anatomic reports are to be found. Yet the herniation of the cerebellum into the foramen magnum, producing pressure paralysis of medullary cardiorespiratory centers, is probably the commonest immediate cause of death in cases of intracranial compression.

The need of more accurate diagnostic criteria for this syndrome has occurred to me, particularly for early or partial block of the foramen. By establishing an early diagnosis of impending block, one can often by appropriate therapy prevent the inevitable medullary paralysis.

In a number of cases in which I had suspected herniation, I found a disturbed pressure relationship on spinal or cisternal puncture, also in certain fatal cases in which herniation was later proved at necropsy. These observations have led me to believe that there are manometric signs indicative of this obstruction. While subarachnoidal punctures are technically contraindicated in these states of block, there are times when punctures are necessary. In other cases in which the condition is not suspected at the time of puncture, the block, if discovered, may be relieved by early treatment.

The earliest anatomic reports of cerebellar herniations I found between the years 1905 and 1911. Alquier¹ reported two cases of cerebellar herniation in brain tumor. Wolbach² reported multiple small hernias of the cerebrum and cerebellum into venous sinuses from the swelling of brain tumors but made no mention of larger herniations into the foramen magnum. Laignel-Lavastine³ reported a case of cerebellar herniation into the vertebral canal, but he believed this to be a postmortem condition caused by intracranial injection of solution of formaldehyde under pressure. A tumor was not present in this case.

In 1920, Adolf Meyer⁴ reported ten interesting cases with illustrations showing herniation in brain tumors and other conditions of brain swelling occurring either under the falx cerebri, under the tentorium cerebelli or into the foramen magnum. In five of his cases, foraminal wedging was a prominent finding and apparently the immediate cause of death. In one case the herniation had carried the vertebral arteries about 5 cm. below the foramen, producing a loud vascular bruit.

There are numerous reports in the literature of sudden deaths following spinal or cisternal punctures and also sudden deaths in pressure states such as cerebellar cysts. A large percentage of these deaths can be analyzed as being the result of cerebellar wedging of the medulla with resultant paralysis. Reuter⁵ reported a death occurring thirty minutes after a cisternal puncture that produced cerebellar herniation. Taylor⁶ reported a case of posterior fossa tumor. The patient, following lumbar puncture, had a violent increase in headache, four days later, after a second puncture, sudden collapse, cyanosis and respiratory failure ensued. Artificial respiration was kept up until a temporal decompression could be performed, which somewhat relieved the patient, but three days later he died. At necropsy a cerebellar cyst with a pressure cone into the foramen magnum was found.

Knox⁷ reported five cases of cerebellar cysts, three of which terminated in sudden death. Of these, one case in which necropsy was performed four days after a lumbar puncture showed a marked cerebellar herniation.

Reuben⁸ described a series of cases with meningitic pressure syndromes of the posterior fossa, assumed to be localized cisterna magna pressure, as relieved by spinal drainage. But experience has shown the grave risk of such treatment.

Cisternal or spinal punctures are, therefore, always contraindicated in the pressure lesions of the posterior fossa, although often a diagnosis cannot be made without cerebrospinal fluid studies. Elsewhere I⁹ have outlined cerebellar herniation as one of the contraindications and dangers of cisternal punctures.

Keegan and I¹⁰ have reported cases of cortical herniation into arachnoid granulations producing a thrombosis of the motor cortex and the larger prechiasmatic bodies from increased pressure and a cerebral aneurysm. In this case there was herniation of the cerebellum into the foramen magnum as the immediate cause of death.

So far the diagnostic value of Queckenstedt's sign, an absence of rise of pressure in lumbar puncture on bilateral jugular compression, has been limited to spinal subarachnoid block and the lateral sinus. The absence of response on compressing one jugular vein has been used to determine obstruction of the lateral sinus (Aver-Tobey, Queckenstedt). Several observers¹¹ have reported that tumor compressing the lateral sinus produced this sign. My investigation of the literature does not reveal any definite diagnostic signs for foramen magnum block.

Lurje¹¹ studied Queckenstedt's test in tumors of the posterior fossa. In a case of fourth ventricle tumor he found evidence of a partial block by compressing the jugular veins. With the patient's head flexed he developed a slight increase in pressure, but with the head hyperextended he found no increase in pressure with jugular compression. In other posterior fossa tumor cases he found three showing a positive Queckenstedt sign on one side, indicating a neoplasm in the region of the lateral sinus. He mentions the danger of compression of the cerebellum into the foramen magnum but does not describe any diagnostic localizing signs for block of the foramen magnum.

Kindler¹² described cisternal block and the various conditions in the posterior fossa that obstruct the cisterna magna, including compression of the cerebellar tonsils into the foramen magnum. He reports a case of tumor of the cerebellopontile angle which blocked the posterior fossa basilar cisterna. He localized the tumor by ventriculography after showing the block at the level of the cisterna magna by combined lumbar and ventricular punctures. He gave the characteristics of cisternal block as no fluid obtained by cisternal puncture, positive Queckenstedt sign, and increased protein content in the lumbar fluid. In the terminal stage he found extreme occipital headache associated with extreme opisthotonos and Cheyne-Stokes breathing. He believes that ventricular drainage which relieved the symptoms, is indicated in this type of case.

All these reports indicate the frequency of this important complication of increased intracranial pressure.

The following are cases that have been observed in the past few years by Dr. G. A. Young, myself and other members of the staff of the University of Nebraska College of Medicine. These cases have served to impress on us the necessity of constantly considering the possibility of this serious complication of foramen magnum block in either acute or chronic increased intracranial states.

CEREBROSPINAL FLUID PRESSURE IN OBSTRUCTION OF THE FORAMEN MAGNUM

FATAL CASES OF MENINGITIS

CASE 1—*Post traumatic meningitis*. A young man was observed in the terminal stage of a pneumococcal meningitis following a skull fracture. Lumbar puncture pressure was

12 Kindler, W. The Recognition and Significance of Cisternal Block. *Monatschr. f. Ohrenh.* 63: 204 (Feb.) 1931.

subnormal and fluid was obtained only by aspiration. Cisternal puncture also showed a subnormal pressure, compression of either jugular vein caused a slight increase in pressure but bilateral jugular compression stopped the flow entirely. The tests suggested a cerebellar herniation. At necropsy a diffuse meningitis and definite coning of the cerebellum was found about the medulla but not sufficient to produce a complete wedging block of the foramen magnum.

CASE 2—*Type II pneumococcal meningitis from ethmoid sinusitis*. A young man, seen early in the infection was treated by continuous spinal drainage and forced hypotonic intravenous solutions and intracarotid Felton's pneumococcus serum. In the terminal state poor spinal drainage was noted. At necropsy a diffuse meningitis secondary to suppurative ethmoiditis was found with a herniated cone of the cerebellum into the foramen magnum.

CASE 3—*Meningococcal meningitis*. A child aged 5 years was first treated on the fourth day of the infection. After seventy-two hours of alternate cisternal and lumbar serum injections the fluid was sterile and the infection appeared under control. Difficulty in removing enough cerebrospinal fluid to give serum was noted. The cisternal fluid at the last puncture was blood tinged. Increased head retraction, dysphagia, shallow rapid respirations and cyanosis were developing. Cerebellar herniation was suspected and hypertonic dextrose dehydration therapy was ordered. The intern's delay of several hours in carrying out orders found the patient already moribund and the child died during the dextrose administration. At necropsy the meningitis appeared entirely relieved but there was a marked pressure cone of the cerebellum into the foramen magnum with petechial hemorrhages of the pia mater in about the rim of the herniated cone. Death was caused by a mechanical block of the foramen magnum with resultant medullary paralysis from cerebral edema. Earlier administration of dextrose would have prevented this death.

CASE 4—*Streptococcal otitic meningitis from suppurative petrositis*. Following a lumbar puncture the patient's pulse became slow, and increased pain developed in the neck with head retraction. The pulse became irregular, dysphagia was noted, and death followed within twenty-four hours. At necropsy a petrous apex abscess with invasion into the internal carotid artery was found. This produced diffuse meningitis and a marked pressure cone of the cerebellum into the foramen magnum.

CASE 5—*Streptococcal otitic meningitis from suppurative thrombophlebitis*. A boy, aged 6 years, died of meningitis following suppurative mastoiditis and lateral sinus thrombosis. Extensive intracarotid treatment in the form of irrigation of iodine with hypotonic intravenous solutions to produce forced spinal drainage was used. This treatment increased the cerebral pressure and forced the cerebellum into the foramen magnum. The patient had attacks of slow respirations and cyanosis. At necropsy these critical signs were found. The cerebellum was herniated into the foramen magnum. Hypertonic intravenous dehydration was used but of no avail. Death occurred within twenty-four hours. At necropsy lateral sinus thrombosis was found. The foramen magnum was not produced.

This case and case 2 were treated with forced hypotonic intravenous solutions and use of forced hypotonic solutions.

FATAL TUMORS

CASE 6—*Third ventricle tumor*. The onset of intracranial pressure was noted. The neurologist observed a large arachnoidal hemorrhage with lateral displacement of the midline. Lumbar puncture revealed 12 mm. of pressure. Compression gave a normal pressure. The left jugular vein gave no response. Pain in the head. The diagnosis was acute medullary paralysis. Encephalography was done. The tumor was found with herniation into the foramen magnum.

continuous observation of the patient for a least the first twenty-four hours. During convulsions the inhalation of amyl nitrite may be prolonged to a minute or slightly longer. When respiration and heart rates show little or no abnormality, the administration of amyl nitrite should be reduced to once every several hours. To combat severe headaches that may occur an analgesic with no depressive action on respiration may be employed.

Our study on other nitrites is in progress, but a priori they offer disadvantages: the decomposition of an aqueous solution such as that of sodium nitrite, the explosive nature of organic nitrates, the necessity of repeated intravenous injections and the risk of introducing into the circulation an overdose of a fixed drug. Unless a member of the same group proves to have a higher therapeutic efficiency it seems better to use amyl nitrite, which is rapid in action, easy to administer by inhalation, and readily available.

Keegan and I¹⁰ have reported a case of cortical herniation into arachnoid granulations producing a thrombosis of the motor cortex into the larger pacchionian bodies from increased pressure of a cerebral aneurysm. In this case there was herniation of the cerebellum into the foramen magnum as the immediate cause of death.

So far the diagnostic value of Queckenstedt's sign, an absence of rise of pressure in lumbar puncture on bilateral jugular compression, has been limited to spinal subarachnoid block and the lateral sinus. The absence of response on compressing one jugular vein has been used to determine obstruction of the lateral sinus (Ayer-Tobey, Queckenstedt). Several observers¹¹ have reported that tumors compressing the lateral sinus produced this sign. My investigation of the literature does not reveal any definite diagnostic signs for foramen magnum block.

Lurje¹² studied Queckenstedt's test in tumors of the posterior fossa. In a case of fourth ventricle tumor he found evidence of a partial block by compressing the jugular veins. With the patient's head flexed he developed a slight increase in pressure, but with the head hyperextended he found no increase in pressure with jugular compression. In other posterior fossa tumor cases he found three showing a positive Queckenstedt sign on one side, indicating a neoplasm in the region of the lateral sinus. He mentions the danger of compression of the cerebellum into the foramen magnum but does not describe any diagnostic localizing signs for block of the foramen magnum.

Kindler¹² described cisternal block and the various conditions in the posterior fossa that obstruct the cisterna magna, including compression of the cerebellar tonsils into the foramen magnum. He reports a case of tumor of the cerebellopontile angle which blocked the posterior fossa basilar cisterna. He localized the tumor by ventriculography after showing the block at the level of the cisterna magna by combined lumbar and ventricular punctures. He gave the characteristics of cisternal block as no fluid obtained by cisternal puncture, positive Queckenstedt sign, and increased protein content in the lumbar fluid. In the terminal stage he found extreme occipital headache associated with extreme opisthotonos and Cheyne-Stokes breathing. He believes that ventricular drainage, which relieved the symptoms, is indicated in this type of case.

All these reports indicate the frequency of this important complication of increased intracranial pressure.

The following are cases that have been observed in the past few years by Dr. G. A. Young, myself and other members of the staff of the University of Nebraska College of Medicine. These cases have served to impress on us the necessity of constantly considering the possibility of this serious complication of foramen magnum block in either acute or chronic increased intracranial states.

CEREBROSPINAL FLUID PRESSURE IN OBSTRUCTION OF THE FORAMEN MAGNUM

FATAL CASES OF MENINGITIS

CASE 1—*Post traumatic meningitis*. A young man was observed in the terminal stage of a pneumococcal meningitis following a skull fracture. Lumbar puncture pressure was

subnormal and fluid was obtained only by aspiration. Cisternal puncture also showed a subnormal pressure, compression of either jugular vein caused a slight increase in pressure but bilateral jugular compression stopped the flow entirely. The tests suggested a cerebellar herniation. At necropsy a diffuse meningitis and definite coning of the cerebellum was found about the medulla but not sufficient to produce a complete wedging block of the foramen magnum.

CASE 2—*Type II pneumococcal meningitis from ethmoid sinusitis*. A young man seen early in the infection was treated by continuous spinal drainage and forced hypotonic intravenous solutions and intracarotid Felton's pneumococcus serum. In the terminal state, poor spinal drainage was noted. At necropsy a diffuse meningitis secondary to suppurative ethmoiditis was found with a herniated cone of the cerebellum into the foramen magnum.

CASE 3—*Meningococcal meningitis*. A child aged 5 years was first treated on the fourth day of the infection. After seventy-two hours of alternate cisternal and lumbar serum injections the fluid was sterile and the infection appeared under control. Difficulty in removing enough cerebrospinal fluid to give serum was noted. The cisternal fluid at the last puncture was blood tinged. Increased head retraction, dysphagia, shallow rapid respirations and cyanosis were developing. Cerebellar herniation was suspected and hypertonic dextrose dehydration therapy was ordered. The intern's delay of several hours in carrying out orders found the patient already moribund, and the child died during the dextrose administration. At necropsy the meningitis appeared entirely relieved, but there was a marked pressure cone of the cerebellum into the foramen magnum with petechial hemorrhages of the pia membrane about the rim of the herniated cone. Death was caused by a mechanical block of the foramen magnum with resultant medullary paralysis from cerebral edema. Earlier administration of dextrose would have prevented this death.

CASE 4—*Streptococcal otitic meningitis from suppurative petrositis*. Following a lumbar puncture the patient's pulse became slow and increased pain developed in the neck with head retraction. The pulse became irregular, dysphagia was noted and death followed within twenty-four hours. At necropsy a petrous apex abscess with invasion into the meninges produced diffuse meningitis and a marked pressure cone of the cerebellum into the foramen magnum.

CASE 5—*Streptococcal otitic meningitis from lateral sinus thrombophlebitis*. A boy, aged 6 years, developed meningitis following suppurative mastoiditis and lateral sinus thrombosis. Extensive intracarotid treatment in the form of Pregl's solution of iodine with hypotonic intravenous Ringer's and dextrose solutions to produce forced spinal drainage was carried out. This treatment increased the cerebral edema, and poor drainage from either lumbar or cisternal puncture was noted. Signs of cerebellar-magnum obstruction occurred in the form of cyanotic attacks, slow respirations, and syncope. On two occasions after these critical spells, the patient rallied remarkably following hypertonic intravenous dextrose injections. The patient finally died of spreading encephalitis and medullary failure. At necropsy, subdural abscess near the cranial vault, diffuse meningitis, lateral sinus thrombosis and a compression ring at the foramen magnum not producing a complete block were noted.

This case and case 2 illustrate the danger of increasing cerebral edema and medullary compression by the use of forced hypotonic solutions.

FATAL TUMOR CASES

CASE 6—*Third ventricle tumor*. The patient had a sudden onset of intracranial pressure symptoms following a head injury. The neurologic observations were suggestive of a subarachnoid hemorrhage with latent hematoma. Cisternal puncture revealed 12 mm of mercury pressure. The right jugular compression gave a normally active response, compression of the left jugular vein gave a delayed response with increased pain in the head. The fluid was yellow. The patient developed acute medullary paralysis with sudden death six hours after encephalography. At necropsy, third ventricle glioma was found with hemorrhage into the tumor and recent hemorrhage into the ventricles with cerebellar herniated cone.

¹² Kindler W. The Recognition and Significance of Cisternal Block. *Monatsschr. f. Ohrenh.* 65: 204 (Feb.) 1931.

CASE 7—Right subcortical tumor with right ptosis and left hemiparesis This patient was observed first on account of sensory jacksonian convulsions and nine months later in a terminal coma. Pressure symptoms or localizing signs were absent until two weeks before death. Cisternal puncture revealed the initial pressure to be 12 mm of mercury. No response occurred on bilateral jugular compression, but as the jugular compression was released there was a prompt rise up to 20 mm of mercury. On a second bilateral jugular compression the pressure fell a few millimeters from 20 mm and on release of jugular compression the pressure rose promptly to 30 mm. After that the jugular compression failed to show these bizarre phenomena. After removal of a few cubic centimeters of fluid, the pressure dropped promptly to 10 mm of mercury.

These results indicated a partial intermittent block with a disturbance of the normal hydrodynamics, a bizarre Queckenstedt response of partial subarachnoidal block and also a reversed Queckenstedt sign with a secondary rise indicative of ball valve or partial obstruction at the foramen magnum.

CASES OF RECOVERY

CASE 8—Midbrain tumor not confirmed A girl, aged 6 years, gradually developed a midline cerebellar syndrome of pressure type (choked disks lateral and vertical nystagmus, vomiting suboccipital pain and bilateral ataxic signs). A cerebellar decompression was performed by Dr J J Keegan. After tapping the ventricle, he found no tumor. The block undoubtedly was of the cerebral aqueduct. The cerebellum was herniated down to the second cervical vertebra. In this case there had been a slow development of cerebellar herniation producing only cerebellar symptoms without symptoms of acute medullary compression. This type of case undoubtedly would have a fatal ending from spinal puncture.

CASE 9—Meningococcus meningitis An adult patient was observed shortly after case 3. During the course of intracisternal and spinal serum therapy there occurred definitely increased rigidity of the neck with occipital pain. The pulse dropped to 50. The symptoms were made worse by attempted drainage. One hundred and fifty cubic centimeters of 50 per cent dextrose was given three times at eight-hour intervals. Clinical improvement was marked, leading to recovery. Apparently an early cerebellar-magnum block was relieved by hypertonic dextrose.

CASE 10—Meningococcus meningitis A girl, aged 5 years entered the hospital three days after the onset of the meningitis. After two spinal serum injections the child suddenly refused fluids, the pulse dropped to 62 and the temperature to 96 rectal. The child was more restless, crying out with pain, and the neck showed increased retraction. The pulse continued slow and irregular. A cisternal puncture showed a low pressure without a good response on bilateral compression of the jugular vein. Only 75 cc. of cerebrospinal fluid was obtained and about 5 cc. of serum was given. Respiratory irregularity and cardiac arrhythmia developed immediately following the puncture. The patient's condition was very poor, attacks of cyanosis developed, the respirations were very slow and deep, and the patient became comatose. Fifty cubic centimeters of 50 per cent dextrose was given in the vein at once. At the end of the injection the child had a severe generalized convulsion and the respiration ceased. Hypodermic stimulation and artificial respiration with oxygen were given with the head lowered. Another 50 cc. of 50 per cent dextrose was given while the child looked as though she was dying. After some minutes the cardiac action improved and the respirations returned, at first irregularly and later normally. The lumbar administration of serum was begun twenty-four hours after this attack, and the patient made a normal recovery. This is another example of acute cerebral edema with mechanical block of the foramen magnum and medullary paralysis in which the hypertonic dextrose was undoubtedly life saving. Its use in meningitis has become almost routine.

CASE 11—Cerebral aneurysm, meningeal apoplexy A patient developed a typical spontaneous meningeal apoplexy. The first cisternal puncture revealed a uniformly bloody fluid under 14 mm. of mercury pressure. Jugular compression gave normal results and a usual drainage was done. Lumbar puncture,

twenty-four hours later, revealed 30 mm of mercury pressure on compression of either jugular vein. A prompt drop in pressure to 20 mm occurred, but with bilateral compression of the jugular vein the pressure rose slowly to 40 mm. After removal of 5 cc. the pressure dropped to 10 mm of mercury, nystagmus and increased rigidity of the neck were noted. Further drainage was discontinued and hypertonic intravenous dextrose with magnesium sulphate was given by rectum with complete relief of symptoms.

This case in which there was undoubtedly an early potential ball valve block, demonstrates, along with case 7, an apparently new sign, namely, a reversed Queckenstedt phenomenon, which seems to be diagnostic of partial cerebellar herniation into the foramen magnum. Its presence always contraindicates further spinal or cisternal punctures and indicates active dehydration therapy to prevent serious medullary paralysis.

CASE 12—Brain swelling, etiology undetermined, cerebellar herniation, relieved by ventricular puncture A woman, aged 28, entered the Douglas County Hospital with a vague history of chronic headache, lethargy and vomiting. At first the patient was treated as showing a catatonic psychotic reaction. A variable pulse rate developed, at times 48 and 60, at other times 160. Dysphagia and nystagmus were noted. A spinal puncture showed a pressure of 28 mm of mercury (jugular phenomena were not observed). Medullary symptoms became more pronounced and the neurologic examinations showed normal optic disks, nystagmus, neck rigidity, bilateral hypotonia and ataxia. Severe suboccipital pain was present. A cisternal puncture showed a low pressure, from 8 to 10 mm of mercury with no response on jugular vein compression. Three injections of 150 cc. of 50 per cent dextrose did not improve the patient. She appeared critically ill, was more lethargic and vomited. The pulse was weak and rapid and the neck retraction extreme. Ventricular puncture was performed by Dr J J Keegan. The ventricles were apparently not dilated. The needle was left in place three days for drainage. Almost immediately the patient's condition improved, the pulse regained normal rate and volume, the headache disappeared and the patient has gradually become mentally alert. The etiology is still undetermined. The blood Wassermann reaction was 4 plus the spinal reaction normal. The patient's general condition improved on treatment for syphilis.

COMMENT ON CASES

The frequency of pressure herniation with partial obstruction of the foramen magnum as a complication of meningitis cannot be too strongly emphasized. Spinal block is spoken of frequently in articles on meningitis. In my experience, adhesive or fibrinous exudative blocks are rare and in acute stages never found. The obstruction is undoubtedly due to an acute cerebral edema producing medullary compression at the foramen magnum, obstructing the subarachnoidal flow into the spinal canal. Early deaths in meningitis are frequently caused by this obstruction producing medullary failure.

Increasing occipital pain, not relieved by drainage, or increased neck pain with head retraction, and any medullary symptoms such as disturbance of the pulse, respiratory ratio, dysphagia or vomiting justify a diagnosis of cerebrospinal fluid block at the foramen magnum. Any abnormal pressure phenomenon, an absence of response on jugular compression, a sudden drop in the pressure reading, a reversed or bizarre Queckenstedt sign, clinches the diagnosis and calls for immediate dehydration therapy and at times ventricular drainage to save life.

A large number of these cases were seen before we had noted the bizarre or reversed Queckenstedt sign, so we cannot state whether it was present in these cases. Frequently, jugular compression studies were not carried out. This fact illustrates the need for a routine type

of pressure study to be carried out in all spinal or cisternal punctures

In two instances (cases 2 and 5) it was observed that use of hypotonic solutions for the purpose of forcing spinal drainage must be watched carefully because of the danger of cerebral edema, leading to medullary compression. One must be ready in the face of symptoms of herniation to reverse the process and give hypertonic dehydrating therapy.

In chronic, slowly developing intracranial pressure states, marked cerebellar herniation may gradually occur without producing acute medullary compression symptoms but will show itself clinically as a midline cerebellar syndrome. This syndrome is demonstrated in case 8.

All spinal cisternal punctures or drainages are contraindicated in the face of cerebellar herniation and frequently lead to early, fatal medullary paralysis.

OUTLINE OF SYMPTOMS AND SIGNS OF CEREBELLAR HERNIATION

1 Severe suboccipital pain, radiating up to the ears, increased by head movement

2 Increasing head retraction or opisthotonos occurring in children, a fairly complete block

3 Slow pulse, cardiac arrhythmia, attacks of cyanosis, mottled skin

4 Respiratory arrhythmias, from slow deep respirations to Cheyne-Stokes type

5 Dysphagia, refusal of fluids

6 Forceful vomiting

7 Bruit heard over the occipital region, where there is compression of the vertebral arteries

8 Blood tinged cisternal fluid

PRESSURE SIGNS ON SPINAL OR CISTERNAL PUNCTURE

A Complete block

1 Positive Queckenstedt sign. No response or increased manometric pressure on bilateral jugular vein compression, indicative of subarachnoid block anywhere, in the absence of evidence, for spinal block usually means block of the foramen magnum.

2 Increased spinal manometric pressure at the outset of puncture with a sudden drop to normal or subnormal after removal of a few cubic centimeters of cerebrospinal fluid. This finding shows that a block has been produced by the puncture.

3 After the block has been established, a low pressure, and a cerebrospinal fluid obtained with difficulty or only with aspiration. Such a condition is often thought to be "dry tap."

B Partial or ball valve type of block

1 Slow or delayed response on jugular compression with increase in patient's occipital or head pain.

2 Reverse of Queckenstedt's sign. On compression of either jugular vein a drop in pressure reading instead of a normal rise, with a slow return to the initial reading.

3 Slight fall from the initial pressure on combined bilateral pressure, with a delayed rise after release of the jugular compression to a higher reading than the initial reading.

SUMMARY

The clinical importance of cerebellar herniation into the foramen magnum as a complication and immediate cause of death in acute and chronic intracranial pressure states has been stressed.

A review of the available anatomic, pathologic and clinical observations of this important syndrome in the medical literature has been made.

Clinical, necropsy or cerebrospinal fluid pressure studies were made in twelve cases of acute and chronic compression syndromes. The symptoms and signs of cerebellar herniation with special reference to spinal fluid studies indicating partial and complete subarachnoid block from cerebellar coning or wedging into the foramen have been outlined.

CONCLUSION

Cisternal or spinal punctures are a frequent cause of death and are contraindicated when evidence of this block is found. Immediate dehydration therapy and at times ventricular drainage are indicated in order to prevent fatal medullary paralysis.

The extreme importance of this block as an early cause of death in meningitis has been practically overlooked in the literature. In my experience, the foramen magnum has been the most frequent site of block. I am constantly on the alert to detect its presence and consider intravenous hypertonic dextrose life saving in this condition.

A new manometric pressure sign, namely, a bizarre or reversed Queckenstedt phenomenon, has been observed, which apparently indicates an early partial or intermittent ball valve type of obstruction of the cerebellum herniated into the foramen magnum. It is believed that further observation and use of this sign will enable one to make a diagnosis of impending block and thus to institute proper preventive therapy against fatal medullary compression.

ANTEROLATERAL CHORDOTOMY FOR INTRACTABLE PAIN

EDGAR A. KAHN, MD

ANN ARBOR, MICH

Although Spiller's operation of anterolateral chordotomy has been often performed since 1911 for the control of intractable pain, it may still be said to be a much neglected procedure, the great scope of which has not been recognized by the medical profession.

Historically, Van Gehuchten in 1893 first expressed the definite opinion that fibers conveying pain and temperature sensation passed up the cord in Gowers' tract, although Gowers himself had suggested this in 1879.

No actual proof was afforded until Spiller's¹ fortunate observation of a patient at the Philadelphia General Hospital in August, 1904. This patient showed an almost complete loss of the sense of pain and temperature in the legs, with preservation of tactile sensibility. He was under observation for some months and died in January, 1905. The necropsy revealed a solitary tubercle involving the right tract of Gowers at the extreme lower end of the thoracic cord and slightly above this a second solitary tubercle implicating the left tract of Gowers.

This absolute localization of the pain tracts and the evidence that no important motor or tactile fibers passed

From the Department of Surgery, University Hospital.

through this tract led Spiller in 1911, definitely to propose section of the anterolateral column for intractable pain. The first operation was performed by Martin in 1911 at Spiller's request.² The indication was severe pain in the pelvis and lower limbs from a malignant growth in the spinal cord. The result was only partially satisfactory.

The operation also was performed in Breslau in 1912 by Tietze at Foerster's suggestion, independent of the work of the Americans. The value of the procedure, however, was not generally realized until Frazier,³ in 1920, reported his first series of six cases. The results were satisfactory in five more or less solving the control of pain below the umbilicus. For the control of pain in the upper extremity it was still necessary to do posterior rhizotomies, which produced an anesthetic, worse than useless, arm.

It remained for Foerster⁴ to solve the problem of control of pain in the upper extremity without resorting to rhizotomy. Through a most exact work on the anatomy and physiology of the anterolateral column he demonstrated that pain and temperature fibers on entering the posterior roots cross over immediately on synapsing in the posterior horn or at most ascend one segment before crossing over to run upward in the spinothalamic tract (fig 1). Foerster was thus able to perform a unilateral chordotomy as high as the second cervical segment, with loss of pain and temperature almost to that point (fig 2).

Chordotomy has been performed in the clinic of Dr Max Peet on seventy-eight patients by Drs Peet, S. S. Allen and myself. The first nineteen cases were reported⁵ in detail in 1926. A case of bilateral cervical chordotomy has since been reported.⁶

INDICATIONS

First in importance comes the intractable pain associated with malignant disease (fig 3). In these days of x-ray and radium therapy, the fibrosis produced is often the cause of the most frightful pain. Moreover, radiation can be more radically applied following chordotomy without fear of increasing the suffering. We have performed chordotomy on thirty-three patients for malignant growths of the uterus, prostate and large bowel. The pain of bone metastasis is perhaps the severest of all. We have twice performed the operation for ulcerative cystitis with good results. Other indications are the gastric crises (fig 4) and lightning pains of tabes, phantom limb, osteo-arthritis and traumatic lesions of the spinal cord, and brachial and lumbosacral plexuses. Even intolerable itching can be relieved, although we have never operated for this alone.

TECHNIC

Local anesthesia is the anesthetic of choice, since the sensory level can be tested at the time of the cord incision. Most of our patients, however, have been operated on under tribrom-ethanol anesthesia during the last few years.

We have recently been shortening the length of the incision and find $2\frac{1}{2}$ inches sufficient in slender individuals. Two laminae are removed, but the laminectomy must be wide for proper rotation of the cord. The dura should and usually can be opened without nicking the underlying arachnoid.

Two technical difficulties may now be encountered. The first is a thickened arachnoid adherent to the cord structures. Since the arachnoid must be stripped from the anterolateral column before the cord can be incised, hemorrhage may result. This usually stops readily on the application of cotton pledgets, but the staining of the cerebrospinal fluid and cord structures tends to obliterate landmarks. The arachnoid is always incised laterally. This lateral incision leaves the arachnoid intact over the posterior part of the cord and undoubtedly aids in preventing the formation of adhesions.

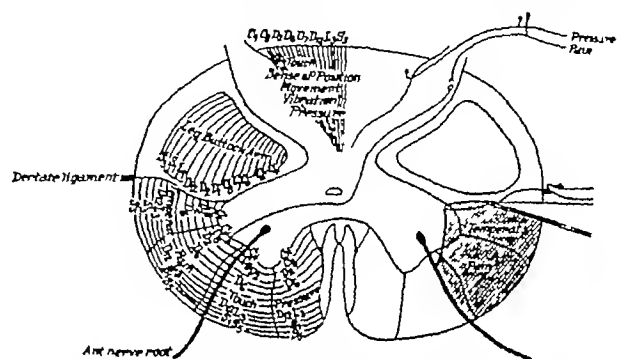

Fig. 1—Schematic drawing showing pointed knife blade entering spinothalamic tract. The dentate is grasped in a hemostat. (Modified from Foerster.)

The dentate ligament is grasped and its dural attachment divided. The second technical difficulty arises when the ligament is not firmly attached to the cord, since rotation of the cord is accomplished by traction on the dentate. Also its line of insertion marks the division between spinothalamic and pyramidal tracts. If rotation is difficult, division of a posterior nerve root may make this easy. This should be avoided if possible in the region of the eighth cervical and first dorsal segments, since an area of true anesthesia may be produced in the hand. If the dentate ligament does not suffice for rotation of the cord, this may be accomplished by traction on an adherent arachnoid or, better, a divided anterior nerve root. A pointed knife with bone wax, marking off from 3 to 5 mm, is then inserted at the line of dentate attachment and emerges through an anterior nerve root. It is most important that the blade be entered parallel to the axis of the transverse diameter of the cord to avoid injury to the pyramidal tract. It should again be stressed that the arachnoid must be removed over the area of cord to be incised. If this is not done, it requires force to enter the knife blade into the cord substance, resulting in tearing off of the dentate ligament from the cord and even damage to the cord itself.

An avascular area is chosen, if possible, for the line of incision. If an avascular area cannot be found, the vessels in their pial attachment may be carefully freed from the cord substance.

It is important that the knife blade emerge through an anterior nerve root. The two failures that I have had to obtain a proper level were shown at reoperation to have resulted from not carrying the incision far enough anteriorly. Carrying the incision too far anteriorly has in several cases, in which it was knowingly

done, resulted in a complaint of numbness of the legs. This seems rather good evidence that many of the fibers carrying tactile sensation lie in the most anterior part of the spinothalamic tract.

Starting the incision back of the dentate would, of course, give permanent pyramidal tract damage. This has not occurred in our series though atrophy of the deltoid resulted in one high cervical cord incision, probably from damage to anterior horn cells from too deep an incision.

CAUSES OF FAILURE

Though our results have on the whole been gratifying, not more than three fourths of them have been really satisfactory. There are a number of contributing factors here.

In the first place, pain is purely subjective. One of the most difficult questions we are all called on to answer is whether or not a patient's pain is of psychogenic origin. In two cases of pain of unknown etiology, one was still unrelieved after three successive chordotomies, a higher level being obtained each time. Even in the presence of organic pathologic changes we cannot be certain that the pain is not imagined or simulated by the patient, perhaps to obtain morphine.

True morphine addiction is conducive to poor results. There have been two and possibly four failures from this source. We have, however, frequently operated on patients taking large doses of morphine who gladly gave up the narcotic as soon as the pain of the laminectomy incision had subsided. There must be a predisposition to drug addiction, mental, physical or both, since some people taking large doses immediately give up morphine when their organic pain is relieved.

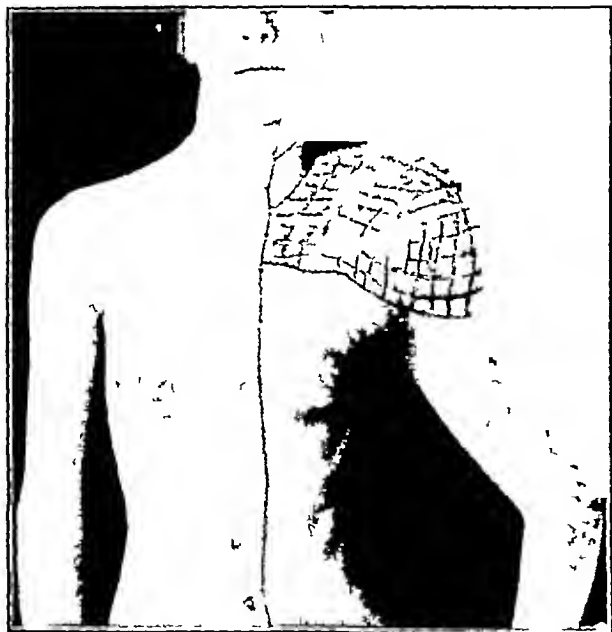

Fig 2—High level of analgesia obtained from section of spinothalamic tract just above the third cervical segment. The cross hatched area represents the total anesthesia obtained from cutting the third, fourth and fifth posterior nerve roots on the left.

The most definite cause of the failure of chordotomy is a level of analgesia below the pain zone. A case of carcinoma of the pericardium and one of gastric crises were not relieved for this reason. At that time, we were unfamiliar with Foerster's work and did not feel safe in making an incision into the spinothalamic tract

deeper than 3.5 mm. We have frequently since made incisions 4.5 and 5 mm in depth.

COMPLICATIONS

Since the incision is ordinarily made in the upper thoracic region, severe pain is usually complained of for a few days postoperatively. This results chiefly from the pull of the shoulders on the incision. The

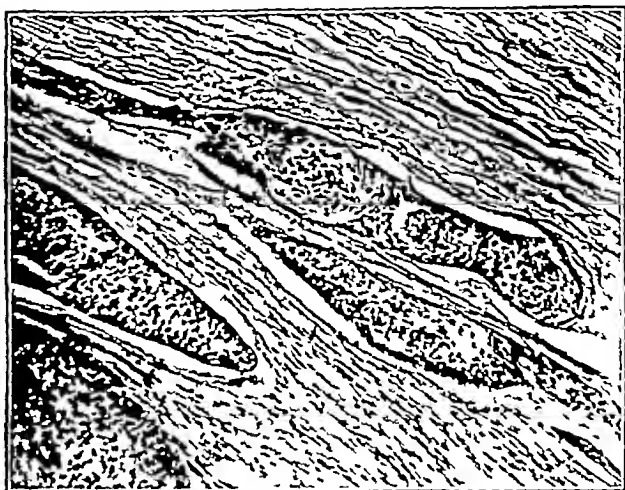

Fig 3—Section of carcinomatous infiltration into sciatic nerve. Complete relief of pain from unilateral chordotomy up to the time of death three weeks later.

pull of the shoulders may also tend to reopen the incision in cachectic individuals. This has happened twice in this series. The smaller incision now being made should decrease this possibility.

Recently we have been making the incision higher in all cases, removing the laminae of the seventh cervical and first dorsal vertebrae for low chordotomy. This has decreased the immediate postoperative pain, by removing the pull of the shoulders.

The pain in the laminectomy incision may make determination of the sensory level impossible for a while after the patient has reacted from the anesthetic. The following case is instructive.

A woman, aged 28, highly intelligent had been operated on elsewhere for what proved to be a cylindroma of the pelvis. X-ray and radium therapy had been used extensively and the pain had become excruciating. She was in a highly nervous state and had slept little for some weeks. Chordotomy was performed, but on reacting from the anesthetic the patient still complained of her old pain. No sensory level could be determined because of lack of cooperation. The following day the wound was reopened and deeper incisions were made. Again on reacting no sensory level could be determined and the pain continued. A few days later a high sensory level was demonstrated. The pain persisted a few more days and then disappeared.

There is little doubt that the first chordotomy was satisfactory.

Because of the analgesia produced and the ordinarily poor state of nutrition of these patients, pressure sores are prone to develop. I feel certain that trophic influences do not enter here. These decubital areas are, however, never painful following bilateral chordotomy, since the analgesia produced extends into the subcutaneous tissues, muscle, fascia and periosteum.

In more than half of our cases of bilateral chordotomy, bladder disturbance in the form of retention has been present. This is especially true when a path-

ologic condition of the pelvis is present. The bilateral cord incision eliminates the sensation of pain and undoubtedly diminishes the remaining bladder sensation. It is even possible that motor tracts to the bladder whose location in the cord is unknown may be damaged. When the added factor of the pelvic disorder, especially infiltration of the posterior bladder wall so common in carcinoma of the uterus, enters, the bladder disturbance is permanent, and constant drainage by an inlying catheter is necessary. We now place an inlying catheter postoperatively as a routine. This avoids the danger of pyelitis, since considerable contractile force is still present in the bladder. The normal bladder function reestablishes itself in the absence of pelvic disturbance in from a few days to a few weeks.

The pain sense in the area originally analgesic may return in from a few weeks to a few years. Temperature sense always returns more quickly than pain sense.

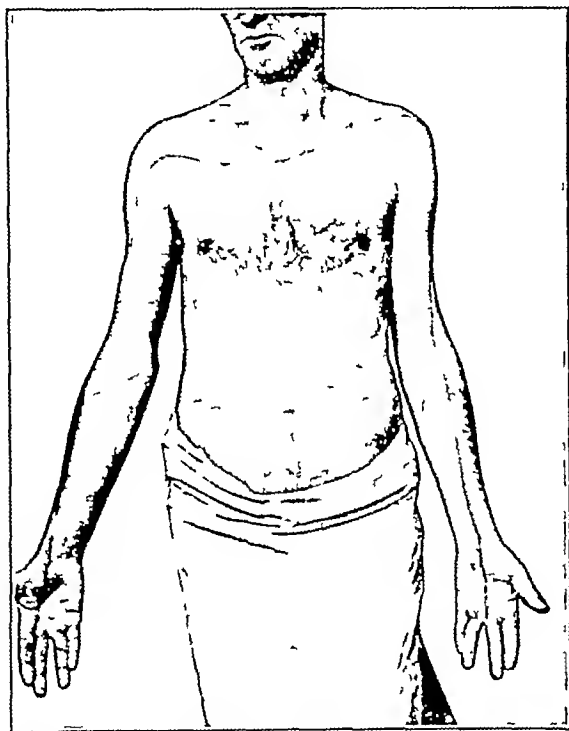

Fig. 4—Area of loss of pain and temperature sense from bilateral chordotomy for gastric crises of tabes. Complete relief of symptoms one year after operation.

We have had four patients with pelvic disorders who had a gradual return of pain, three after two months, the fourth after a year. Since part of the spinothalamic tract extends anterior to the anterior nerve roots, some of the pain sense may be taken over by them. The remainder may come through the posterior column or sympathetics.

When a unilateral chordotomy is done, the pain sense is apt to return quickly. Moreover, when unilateral chordotomy is performed, Foerster has demonstrated a slight but very definite diminution of pain spots on the homolateral side. This is proof that some of the pain fibers ascend in the hemolateral spinothalamic tract. This is especially true of temperature sensation. In unilateral chordotomy, there may be no demonstrable change in temperature sense on the contralateral side. There must be a great deal of individual variation in the arrangement of the spinothalamic tracts.

THE PITUITARY HORMONE INTERMEDIN

AS THE ACTIVE ANTIDIURETIC IN THE TREATMENT OF DIABETES INSIPIDUS. PRELIMINARY REPORT

MARION B. SULZBERGER, M.D.

NEW YORK

In three recent publications, Zondek and his collaborators¹ report that they have demonstrated the presence of a new pituitary hormone—Intermedin. According to them, this hormone is secreted by the pars intermedia of the pituitary gland. They further state that it differs in its reactions to chemical and physical agents and, above all, in its biologic effects from the prolans of the anterior pituitary lobe and the oxytocic and the pressor principle of the posterior lobe. In warm-blooded animals, Zondek and his collaborators demonstrated Intermedin to be present in the entire pituitary gland, in the infundibular stalk and in the walls of the third ventricle. They were unable to demonstrate its presence in any other part of the brain, or in any other tissues or fluids of the body.

Zondek and collaborators state that no specific biologic effects of this hormone have been observed in warm-blooded animals. It is without any of the effects of the other pituitary hormones in human beings.

This is demonstrated by the fact that the Intermedin preparation, which Zondek and Krohn² were able to produce in almost pure aqueous solution (through various chemical and physical procedures that destroyed or eliminated, to a great degree, all the other pituitary hormones and all proteins and impurities), has, until now, been without known specific effect in man or in other mammals.

Prior to the experiments I am about to report, the only demonstration that one was dealing with a specific hormone in Intermedin was through its proved specific action on the pigment-forming cells of certain cold-blooded animals. Zondek and his collaborators have shown that it is a specific pigment hormone and changes the pigmentation of *Phoxinus laevis*, a type of minnow, causing red to appear on the belly, anterior thorax and perioral areas of this fish. (Ordinarily this red coloration is present only during the spawning season.) According to Zondek and his collaborators, this specific Intermedin action cannot be produced by any other hormone. For this reason, they have used this pigment reaction in the fish to standardize their Intermedin preparations, and the quantities of hormone in solution are expressed in phoxinus units. As stated, Zondek and his co-workers found no action of this hormone in normal or diseased persons. They had not used it in diabetes insipidus.

My attention was drawn to the study of the possible effects of Intermedin in mammals and particularly in human beings through the following considerations:

In view of Zondek's work showing that a specific hormone, of as yet undiscovered purpose or function, was to be found in the pituitary gland, in the infundibular stalk and in the walls of the third ventricle, and in these alone, it seemed logical that the action, if any, must take place in these areas. As is well

From the Dermatological Service, Montefiore Hospital for Chronic Diseases.

This investigation precedes certain experiments as to the effects of Intermedin in dermatologic conditions.

¹ Zondek, Bernhard and Krohn, Hans. Hormon des Zwischenlappens der Hypophyse (Intermedin), Klin. Wchnschr. 31, 1293 (July 30) 1932.

known, these parts of the brain include those in which the lesions in diabetes insipidus are considered to be localized.²

Extract of pituitary, prepared from the posterior lobe, is of beneficial action in controlling thirst and urination in diabetes insipidus. As Zondek and his collaborators were able to show, the posterior lobe contains large quantities of Intermedin, and extracts, prepared from posterior lobe substance and not subjected to specific processes for removing Intermedin, must contain, in addition to the posterior lobe hormones, varying quantities of Intermedin.³

These facts and considerations made it seem possible that Intermedin might be the active principle in the treatment of diabetes insipidus and that the posterior pituitary solutions now in use were, perhaps, efficacious to some extent because of their Intermedin content. Should this hypothesis prove true, certain obvious advantages would be gained by treating diabetes insipidus with Intermedin alone. For one could increase the dosage of Intermedin almost as desired, there being no known unpleasant effects such as are produced by the hormones of the posterior lobe, i. e., no contraction of the blood vessels, no spasms of the uterus and intestine, and no increase of blood pressure and of blood sugar.

I employed a pure aqueous solution of Intermedin prepared in the Berlin laboratories of Professor Zondek and there found to be without oxytocic principle, pressor principle or prolactin effects. The preparation was standardized in Berlin and each 1 cc ampule contained 500 phoxinus units of the hormone.⁴

I am indebted to Dr. Sidney P. Schwartz of Montefiore Hospital, who tested the Intermedin preparation for possible harmful effects by injecting 1 cc intravenously in himself. There were no ill effects or effects due to the administration of solution of posterior pituitary.

This result coincided with Zondek's previous observations and I therefore did not hesitate to employ the Intermedin in my two cases of diabetes insipidus.

CASE 1—R. S., a man, aged 41, had been suffering for two and a half years from typical diabetes insipidus. In March, 1932, he underwent an operation for mastoid disease, in which a peculiar fatty tissue was removed from the mastoid cells. The remainder of the personal and family history is not pertinent. There were no roentgenologic changes in the sella turcica and no other signs of disturbed pituitary function. When left without treatment, he was obliged to drink abnormally large quantities of liquid and to urinate approximately every forty-five minutes, day and night.

By means of injections of solution of posterior pituitary, or by intranasal aspiration of posterior pituitary every three to four hours, the tormenting thirst was caused to subside, and the patient urinated at intervals of approximately four hours.

Jan. 15, 1933, the patient sprayed the contents of one-fourth ampule of Intermedin intranasally. This treatment had apparently no effect. The patient's thirst and frequent urination persisted. By taking about 0.25 cc of posterior pituitary extract Obstetrical Parke-Davis through the nasal mucosa, the patient urinated at intervals of from three to four hours, as compared to forty-five minutes.

2 (a) Cushing, Harvey. Pituitary Body, Hypothalamus and Parasympathetic Nervous System. Baltimore: Charles C. Thomas, 1932, pp. 19, 20. (b) In connection with the question of the region probably involved in diabetes insipidus and in consideration of the reports by Zondek concerning the areas in which he found Intermedin, it is of interest to note the observations at autopsy in my case 2 in which the patient died about two months after my experiments. A cavernous hemangioma was present in the hypothalamus. This tumor had destroyed the region of the third ventricle and had compressed the infundibular stalk. The pituitary gland itself was apparently unaffected. (This case is to be reported in detail by Drs. Davison and Selby of the Neurological Division of the Montefiore Hospital.)

3 Zondek and Krolin¹ also found Intermedin in the anterior lobe substance.

4 I am indebted to Professor Zondek for his cooperation without which this work would not have been possible.

January 19, the patient, who had gone without treatment for some time and was urinating at approximately forty-five minute intervals, received a deep subcutaneous injection of 1 cc. of Intermedin. The patient did not urinate until two and a half hours after this injection, then after one hour, and again after one hour.

At 4 p. m., January 28, the patient took a last dose of solution of posterior pituitary intranasally. He began to get very thirsty and to drink copiously at about 7 o'clock. He urinated at 7:45, 8:50, 9:55 and 10:23. At 10:20, he received a deep subcutaneous injection of 2 cc. of Intermedin. The next urination was at 3:20 a. m., an interval of five hours. The following urination was at 6:20. There were no disagreeable or other effects. It must be noted that there were no pituitary effects as previously suffered by the patient after having taken large doses of solution of posterior pituitary. A quantity of solution of posterior pituitary sufficient to prevent urination for five hours caused the patient to exhibit pallor and to have profuse perspiration, palpitations and intestinal cramps.

CASE 2—M. R., a man, aged 31, suffered from typical diabetes insipidus and polyglandular syndrome. The patient was obese and had a feminine type of hair distribution, a basal metabolic rate of minus 41, and a blood pressure of 92 systolic and 56 diastolic. There was no roentgenologic evidence of changes in the sella turcica. According to Dr. Israel Wechsler, to whom I am indebted for placing this case at my disposal, there was neurologic evidence of pathologic processes in the

Observations in Case 2

	Weight		Fluid Intake and Excretion from 9 A. M. to 9 P. M.	
	Pounds	Kilograms	Intake	Excretion
February 9 (without treatment)	212½	96	5 550 cc	6 900 cc
February 10 (without treatment)	210	95	Intake 4,800 cc	Excretion 0 0.0 cc
February 11 (Intermedin injections)	207	94	Intake 2 440 cc	Excretion *2 2.0 cc

* Excretion was reduced to an even greater degree than is shown by these figures for more than 8.0 cc of urine had been voided in the four hours before the Intermedin was injected. The same holds true of the fluid intake.

region of the third ventricle.^{2b} Solution of posterior pituitary and thyroid extract were of uncertain action and without definite beneficial effects.

A record of the observations in an experiment carried out for me on the patient by Dr. Sidney P. Schwartz is given in the accompanying table.

February 11, at 1 p. m., the patient received 2 cc of Intermedin injected deep subcutaneously, the same amount was given at 2:10. Before treatment, the patient had been obliged to take incredibly large quantities of fluid (he was observed to drink 1 600 cc. at one time) and had to urinate with corresponding frequency. After the Intermedin injections, there was an interval of fourteen hours, during which he had no desire to drink or to urinate (from 6 p. m., February 11, to 8 a. m., February 12). The Intermedin injections caused no unpleasant by-effects and had no pituitary-like action.

In this case the Intermedin effect was incomparably better than that which had been achieved by any other therapy, including solution of posterior pituitary.

It seems permissible to conclude from these results that, in the two cases investigated, Intermedin had a marked effect in reducing both intake and output of fluid and thus alleviated the symptoms. Furthermore, although the observations have been restricted thus far to only two cases, it seems significant not only that the effects achieved were striking but that they were proportional to the quantity of Intermedin administered (case 1, 1 cc, two and a half hours without urinating, 2 cc, five hours without urinating, case 2, 4 cc fourteen hours without urinating).

This preliminary report is being submitted in the full realization that the observations will have to be substantiated by observations in further cases and perhaps by animal experiments. For this reason, I do not care to discuss the many obvious practical and theoretical considerations at present. I shall conclude by calling attention to only a few of the more important questions evoked.

Is Intermedin a specific hormone regulating water metabolism? Will it be possible, through increasing the concentration and dosage of Intermedin, to render diabetes insipidus patients comfortable for long periods of time and, perhaps, even achieve some curative effect by aiding certain tissues to recuperate? Is the beneficial effect of solution of posterior pituitary in diabetes insipidus due to its Intermedin content? Should this be the case, it is conceivable that other conditions which are today to some degree benefited by solution of posterior pituitary might be even more favorably influenced by the increased dosage made possible by the administration of pure Intermedin.

200 West Fifty Ninth Street.

PRIMARY CARCINOMA OF APPENDIX WITH GELATINOUS SPREAD

REPORT OF A CASE

MARCUS H. HOBART, M.D.

AND

J. PEERMAN NESSELROD, M.D.

EVANSTON, ILL.

This case of mucous cancer of the appendix, with gelatinous spreading peritonitis, is of primary interest, since a search of the literature revealed very few cases with similar pathologic changes.

Schena¹ reported the case of a man, aged 52, operated on in December, 1928, because of symptoms and signs pointing to involvement of the appendix. Operation revealed a mucous carcinoma of the appendix with gelatinous peritonitis. Appendectomy was performed. Two and a half years later the patient was again operated on for ulcerative carcinoma of the rectum. At this time only slight evidence of the former lesion remained in the pelvis.

Primary carcinoma of the appendix is by no means rare, the average occurrence being 0.39 per cent of all appendices removed.² Up to 1906, only 42 cases had been reported, while by 1929 the number had been raised to 334.³

In spite of this number, "at no time was carcinoma of the appendix diagnosed or suspected." On the other hand, a case was reported as diagnosed rectal cancer with symptoms of rectal and vesical pain, obstinate constipation, loss of weight and strength, and a constricting mass felt in the rectum which showed normal mucosa at biopsy.

5 This remark may also apply to the use of pure Intermedin in treatment of some conditions in which anterior lobe extracts have been used (alopecia etc.). Extracts of the anterior lobe probably also contain appreciable quantities of Intermedin.

From the Department of Surgery of Northwestern University Medical School.

3 Reid, Hugh and Smith, Hugh. Primary Carcinoma of the Appendix. Brit. M. J. 1: 492-493 (March 15) 1930.

At operation, a chronic fibroplastic appendicitis was revealed.⁴

Apparently there are two types of appendical carcinoma, depending partly on its location.

1 At the tip, where it occurs most often, in 90 per cent, the lesion is usually benign, as evidenced by its lack of metastases and by its failure to recur after removal. It was thought that in many cases the origin had been demonstrated to be not from epithelium at all, but from blood vessels. This would constitute actually a benign endothelioma.⁵ Microscopically they show polygonal or spheroidal cells. However, Masson⁶ now gives a modern view of their origin. "Carcinoids" result from the proliferation of the intravenous argentaffin cells of the neurocarcinoid type. They pile up in the nerve fibers, finally rupture their sheaths and infiltrate the tissue of the mucosa and then that of the submucosa. These cases are therefore not cancer at all and are well described as "carcinoids." This type

Fig. 1—Outer aspect of cecum and ileum showing site of removed appendicular tumor and gelatinous metastasis.

of case gives the symptoms of appendicitis and is usually so diagnosed.

2 At the proximal end of the appendix, in 10 per cent, a true malignant tumor occurs. This is not strictly a carcinoma of the appendix but finds its origin in the cecum or ileocecal valve. These tumors metastasize, or simply spread as in the case here reported, and demonstrate all the characteristics of other intestinal malignant growths. Microscopically, they show columnar cells or gelatinous adenocarcinoma. The symptoms here are more likely to simulate those of intestinal obstruction as well as of appendicitis, and because of early symptoms, diagnosis and operation are made earlier.

REPORT OF CASE

A man, aged 65, Jewish, a life insurance agent, came to us complaining of "arthritis" and of a "bloated" stomach after meals both of which had been present for three months. He had had bloody stools at intervals during the past eight months. He had recently gone through a complete physical

6 Masson, P. Significance of Muscular Stroma of Argentaffin Tumors (Carcinoids), Am. J. Path. 6: 499-514 (Sept.) 1930.

and laboratory examination in Chicago, where he had been told that he had arthritis and that his bloody stools were due to hemorrhoids

The patient was very slight and emaciated. There was marked pallor of the mucous membranes and skin, the latter showed a distinct pale lemon tint. The heart was normal in size and shape, but auscultation revealed a soft systolic blow at the apex, not transmitted. The right half of the abdominal wall was definitely rigid. In the right upper quadrant were felt several irregularly shaped firm masses. A rectal examination revealed a firm tumor mass apparently in the anterior wall of the rectum. The examining finger was covered with dark red blood. The reflexes at this time were normal in response.

These observations seemed to warrant a diagnosis of carcinoma of the rectum with metastases to the upper part of the abdomen, which gave a poor prognosis.

Although the case was considered inoperable, hospitalization was advised in the hope that a biopsy of the "rectal" tumor might give further information. On rectosigmoidoscopic examination no tumor could be seen, yet on rectal digital palpation the tumor could be felt easily. The patient was given morphine for the examination and, because of the resulting relaxation of the abdominal wall, several firm irregularly shaped masses could be palpated in all quadrants of the abdomen. Roentgen study of the gastro-intestinal tract was attempted but was unsatisfactory because of the patient's weakness and inability to cooperate. Further examination was deemed inadvisable, as the patient was failing rapidly.

Seven days after leaving the hospital the patient became comatose. A right hemiplegia developed with typical neurologic manifestations. A week later the patient died.

Autopsy presented these essential conditions:

- 1 Primary mucoid carcinoma of the appendix.
- 2 Extensive spreading gelatinous carcinomatosis of the omentum and spleen.
- 3 Subacute thrombotic endocarditis.
- 4 Recent multiple infarcts of the spleen, kidneys and brain.

The subacute thrombotic endocarditis with resulting infarcts was considered the immediate cause of death with the car-

Fig 2.—Colon and greater omentum laden with gelatinous carcinoma.

cina as an accompanying pathologic condition. Thus are presented in one case two distinct clinical and pathologic entities.

Figure 1 represents the outer aspect of the cecum and terminal ileum with glistening gelatinous carcinoma, spreading over nearly the entire specimen. The darkened area near the tip of the cecum is the site of the appendiceal tumor.

In figure 2 is seen the upper half of the ascending colon and all the transverse colon, to which is attached the greater omentum laden with gelatinous carcinoma. The colon can be identified by one of its longitudinal bands and by its appendices epiploicae. In the lower

right-hand corner is seen that portion of the carcinoma laden omentum which happened to lie in the pelvis at the time of the first rectal examination and which led to the first diagnosis of cancer of the rectum. It is easy to understand that this elusive rectal tumor was the mobile omental mass.

Figure 3 illustrates the "lava-like flow" of gelatinous carcinoma over the diaphragmatic surface of the spleen, together with an infarcted area.

Fig 3.—Spleen partly covered with lava like flow of carcinoma. An infarct is also seen.

SUMMARY AND CONCLUSIONS

A rare case of gelatinous carcinoma of the appendix was observed associated with subacute thrombotic endocarditis with multiple infarcts of the spleen, kidneys and brain.

There are two types of carcinoma of the appendix, one, the common (90 per cent) tip carcinoids, practically always benign, the other, the rarer (10 per cent) true or malignant carcinoma of the base, usually arising from the cecum or ileocecal area.

Cancer of the appendix is practically never diagnosed as such before operation.

The fallacy of always trying to cover all the symptoms in a given case by one diagnosis is illustrated by this case with its two distinct clinical and pathologic entities of (1) cancer of the appendix and (2) subacute thrombotic endocarditis with multiple infarcts.

636 Church Street

To See Where We Are—I sometimes wonder if it would help us to close down the laboratories for a while, to hand over the wards to our juniors, and to get together and to try to see where we are. Perhaps we could then marshal our facts—clinical, immunological, and morbid anatomical—see where the gaps are, and begin to make more concerted efforts to fill them. Having done this we might try to dissociate and combine them by deliberation and some constructive thought. The truth is, although science never offered us so many new facts before or so many new instruments for possible exploitation in therapeutics, we seem for the time being less capable than we were of making use of them, except, as I have said, by way of direct action. But the proper adaptation of scientific discovery to therapeutics requires the careful application of physiological principles and a knowledge of the deviations from the physiological that constitute disease. This involves indirect action, which does not fit with the spirit of the times.—Horder, *Lord Annual Oration on New Treatments for Old*, *Brit Med J* 1 859 (May 20) 1933.

Clinical Notes, Suggestions and New Instruments

TONIC LEUKOPENIA WITH RECOVERY FOLLOWING INJECTION OF PENTNUCLEOTIDE

EGBERT L. BURHYTE, M.D., AND EDWIN W. GATES, M.D.
NIAGARA FALLS, N. Y.

A white boy, aged 11 months, seen by one of us, Feb. 9, 1933, was said by the mother to have had a cold for two days. The past and family histories were essentially negative. Examination showed scattered pneumonic patches throughout the right lung. The temperature was 104.8 F by rectum. A diagnosis of bronchopneumonia was made and the child was immediately sent to the hospital.

For the first nine days the course of the disease was rather typical and not worthy of comment. Roentgen examination of the chest confirmed the diagnosis of pneumonia. Examinations of the urine had given essentially negative results. On the second day the blood count showed 80 per cent hemoglobin, 4,500,000 red blood cells and 13,700 white blood cells.¹ Five days after admission the count was as follows: hemoglobin, 82 per cent, red blood cells, 4,600,000, white blood cells, 8,300, polymorphonuclears, 48 per cent, small lymphocytes, 32 per cent, large lymphocytes, 14 per cent, large mononuclears, 0, moderate achromia, normoblasts, 0, megaloblasts, 0, eosinophils, 3 per cent, basophils, 0, transitionals, 3 per cent, neutrophil myelocytes, 0, eosinophil myelocytes, 0. On the tenth day the temperature dropped to normal and remained normal for three days.

On the fourteenth day the temperature suddenly rose to 106.2 F. Physical examination showed a large red swollen papule on the right posterior part of the chest with several small ones on the back and anterior part of the neck. The mouth showed no lesions. The urine was normal and the blood count at 4 p. m. showed white blood cells, 4,200 polymorphonuclears, 4 per cent, small lymphocytes, 63 per cent,

given intramuscularly. The accompanying graph and table show the changing blood picture and the following shows the dosage of pentnucleotide:

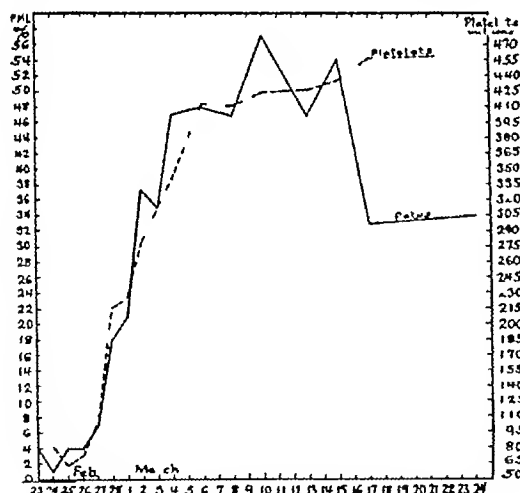

February 24 a. m., 3 cc., p. m., 4 cc.
February 25 a. m., 4.5 cc., p. m., 6 cc.
February 26 a. m., 6 cc., p. m., 4 cc.
February 27 a. m., 4 cc., p. m., 4 cc.
February 28 a. m., 4 cc., p. m., 2.5 cc.
March 1, 2 cc.
March 2, 2 cc.

The blood culture was negative. The temperature was practically normal from one day following that on which it went to 106.2. Progress from then was as follows:

February 23, another large inflamed area was found over the right anterior part of the chest. The right posterior part of the chest remained unchanged.

Blood Counts

Dates	Hemoglobin per Cent	Red Blood Cells	White Blood Cells	Percentage of										
				Polymorphonuclears	Small Lymphocytes	Large Lymphocytes	Large Mononuclears	Eosinophils	Basophils	Transitionals	Neutrophil Myelocytes	Eosinophil Myelocytes	Normoblasts	Megaloblasts

3/17/33	85	4.6	8,500	23	40	9	0	5	0	4	0	0	0	466,000
3/21/33	85	4.6	9,500	24	58	4	0	2	0	2	0	0	0	400,000

The rise in polymorphonuclear leukocytes is shown by the solid line; the rise in platelets by the broken line.

large lymphocytes 22 per cent, transitionals, 11 per cent, moderate achromia. Examination was otherwise negative at this time.

A diagnosis of toxic leukopenia was made and, because of the success which Jackson and his co-workers have had with pentnucleotide, we telegraphed for a supply by air mail. It reached us the following morning and at 11:30 a. m. the child was given a 3 cc. dose followed by a 4 cc. dose that afternoon. As we could find no definite information for dosage in infants we based our dose on that of a 150 pound (68 Kg.) adult and then tripled this for several doses. All injections were

February 24, the lesion on the back was noticeably improved.

February 25, large red papules were found on the anterior part of the neck. The back and anterior part of the chest were improved.

February 27, the lesions of the neck were much larger. The back was draining purulent material.

March 1, the lesions on the back and chest were draining.

March 5, about 1½ tablespoonfuls of pus was obtained from one lesion in the neck.

March 8, an inflamed area showed up on the right buttock.

March 9, another abscess was found beneath the chin.

March 11, all lesions were improving.

March 13, another large abscess formed on the neck. An abscess on the right buttock was opened and a large amount of pus drained.

March 15, considerable pus was obtained from the abscess on the neck. That on the buttock was draining freely.

March 21 all abscesses were healed. The child made an uneventful recovery after this time and was discharged from the hospital, April 4, when his condition was normal.

COMMENT

We report this case because of the very low polymorphonuclear leukocyte count, the marked response to pentnucleotide coming on the fifth day as is often expected, and the failure to develop lesions in the mouth which are frequently found in toxic leukopenia. It is interesting to note that when the polymorphonuclear count was low, the abscesses remained in a quiescent stage and when this count became normal the abscesses rapidly enlarged, several with large quantities of pus.

Recovery was apparently directly due to the specific action of the pentnucleotide on the bone marrow.

¹ All laboratory work was done by Dr. I. M. Walker, pathologist at Niagara Falls Memorial Hospital.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS ADOPTED THE FOLLOWING REPORT

H. A. CARTER, Secretary

DIATHERMY

A Preliminary Statement to Acceptance of Diathermy Apparatus

Diathermy is the therapeutic use of a high-frequency electric current to generate heat within some part of the body. The current employed is greater in frequency than the maximum frequency for neuromuscular response and ranges from several hundred thousand to millions of cycles per second. The spark gap diathermy and the vacuum tube oscillator are the two general types of units manufactured. For the physical characteristics of high frequency currents see the Handbook of Physical Therapy, page 382.

For want of better terminology, diathermy may be divided into two divisions: medical diathermy and surgical diathermy. The term "surgical diathermy" appears to be becoming obsolete and the term "electrosurgery" is taking its place.

Medical diathermy is the production of heat for therapeutic purposes in body tissues, insufficient in amount, however, to produce temperatures high enough to destroy the tissues or impair their vitality. The available evidence indicates that the therapeutic effects are limited to the heat produced. The reader is referred to the Handbook of Physical Therapy or other Council accepted publications for the therapeutic indications of diathermy currents.

Medical diathermy cannot be considered a specific cure for pneumonia. Many physicians have used it and believe it to be a helpful therapeutic adjunct. One fairly constant response to the use of diathermy in pneumonia is the relief of pain. The degree and duration of this relief vary in different patients. Further clinical evidence must be accumulated to substantiate its efficacy for pneumonia.

Hyperpyrexia, the elevation of body temperature by artificial means, is still undergoing investigation. Here again further clinical evidence must be accumulated to substantiate its efficacy in the treatment of disease.

The following are some of the special safety rules for medical diathermy as given in the Handbook of Physical Therapy:

Before applying electrodes inspect carefully the parts to be treated to make sure that the continuity of the skin is nowhere broken and that the heat sensation of the patient is normal.

Before turning on the current from the main inlet inform the patient that all the sensation he can expect is that of mild heat. Instruct the patient to report any uncomfortable faradic sensation, pricking or burning at once.

Do not try to raise the current to the maximum amount of toleration during the first few treatments. Patients often are burned in their endeavor to show how much current they can stand. Remember the principle that a moderate amount of heat applied for a longer period is more effective than pushing up to the limit of tolerance for a shorter period.

If at any time during the treatment the patient complains of an uncomfortable sensation anywhere, turn off the controls, shutting off the main current inlet in case of emergency and if necessary take off and inspect and reapply the electrodes. When inspecting or adjusting electrodes be sure that the current is turned off and increased gradually again after such a procedure.

Do not leave the patient alone during treatment unless arrangements have been made so that the patient himself can turn off the current at any time.

Medical diathermy is contraindicated (1) in acute inflammatory processes such as acute non-draining cellulitis, acute arthritis characterized by infection, and acute pelvic infection; (2) in any condition in which there is a tendency to hemorrhage, such as a gastric ulcer, and (3) in those areas in which the appreciation of heat has been impaired or lost, as in certain peripheral nerve injuries. It is also contraindicated in diseases or injuries in which simpler methods of applying external heat give satisfactory results.

Surgical diathermy is the use of high frequency electric oscillations in such a way that animal tissues are destroyed. By adjusting the widths of the spark gaps or inductance of the high frequency oscillatory circuit and selecting the proper terminals

electrocoagulation and electrodesiccation currents may be obtained in a spark gap machine.

Electrocoagulation is the coagulation of tissues by high frequency current. The heat producing the coagulation is generated within the tissues to be destroyed.

Electrodesiccation is the drying up of cells and tissues by means of short high frequency electric sparks.

The advantages of electrosurgery lie in effective destruction in loco of tissues that it is desirable to eliminate. This manifestly includes many forms of malignancy.

Hemostasis is easily effected in severing vessels up to about 1 mm in diameter either by the application of the coagulating electrode direct or by the intermediary of a well pointed hemostatic clamp, isolating the vessel.

Although the surgical removal of tonsils is to be preferred in certain selected cases the electrosurgical method has proved of value in tonsillectomies in patients presenting contraindications for ordinary surgical procedures such as cardiac disease and advanced age. The destruction of the tonsil is effected in several stages by applying the current alternately first to one side and then to the other, at intervals of one or two weeks. Such patients are usually ambulatory. The method is by no means simple and only skilled surgeons should attempt it. Those operators unfamiliar with the intensity of the high frequency currents and their depth of penetration may easily carry destruction into deep-seated structures adjacent to the disease areas. Especially is this true of blood vessels (a carotid for example) leading to and from the part of traversing neighboring tissues.

For further comments on electrosurgery the reader is referred to the Handbook of Physical Therapy, page 402, or other Council accepted publications.

From time to time the Council will report on the investigation of diathermy machines manufactured by various companies.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

PAUL NICHOLAS LEECH, Secretary

ALPHA-LOBELIN NOT ACCEPTABLE FOR N N R.

Alpha-Lobelin is an alkaloid of *Lobelia inflata* (distinguished from beta-lobelin and lobelidine) marketed by Ernst Bischoff Company, Inc., in the form of the hydrochloride in ampules containing $\frac{1}{10}$ grain and $\frac{1}{20}$ grain. The firm presented the product for consideration of the Council in 1925. The Council adopted a report postponing further consideration because of insufficient evidence of the therapeutic value of the drug. The Council also adopted a report recommending the publication of a preliminary report on Alpha-Lobelin. This preliminary report (THE JOURNAL, Aug 27 1927, p 693) calls attention to the numerous incomplete and usually uncritical, clinical reports which have appeared. Special attention is called to a partial list of hospitals using Alpha-Lobelin in which 183 hospitals and institutions in the United States and Canada were enumerated as using this substance. The Council corresponded with a considerable number of these institutions in order to learn the results of their experience with Alpha-Lobelin. One of these reported that it had been used twenty-four times in moderate asphyxia neonatorum, or markedly delayed breathing, and that with the exception of one case it had not been possible to attribute any beneficial results directly to the drug. The present referee points out that the drug was probably used by intramuscular injection, which method is criticized by Wilson. The Council's preliminary report also states that the paper by Norris and Wells represents the most complete and critical report, both experimental and clinical, that has appeared on the subject. While the report was being considered, the Council's attention was called to the sensational newspaper reports of the work of Camp was cited.

as showing that the pharmacology of Alpha-Lobelin is closely similar to that of nicotine, that an analysis of its action shows that it exerts a weak nicotine action throughout the body.

Ernst Bischoff Company Inc., requested further consideration of Alpha-Lobelin (July 20, 1932), and submitted 108 pieces of advertising. These vary from a leaflet of only a few words up to a volume of 191 pages. Many of these pieces of advertising consist mainly of mere repetitions, and nearly all of them contain citations from the same authors together with reproductions of two tracings one of which was made by Behrens and Pulewka. The Council's referee reported that he had read many of the articles but could not afford the time required to read all of them with the innumerable repetitions of the work of Wieland or Behrens and Pulewka oftentimes introduced in such a way that it is impossible for the casual reader to know whether a given statement is quoted or made by the author. Among the advertising is a blue covered paper circular of forty pages. In this Behrens and Pulewka's tracing, showing resuscitation in carbon monoxide poisoning is repeated five times, another set of tracings three times, and a pair of curves by Wieland and Mayer are repeated twice in such a way that its origin is not clear. This advertising contains what purports to be six papers written wholly or in part by Kurt Peters of New York, nearly all of which are stated to have been read before the New York Academy of Medicine, but much in these articles consists of repetitions of the general statement made in the first section of the report presumably by the manufacturer, sometimes verbatim without credit. Several of the articles in this blue book are carelessly written and bear earmarks of having much of the material supplied by the manufacturer. On page 5 occurs *lobelia inflata*, on page 26 occurs '*lobelia in flata*'. Similarly it is stated on page 23 that Alpha-Lobelin was prepared by the chemist Heinrich [should be Heinrich Wieland] and studied pharmacologically by his brother Hermann. Reichle states (page 24) that

The pharmacologists Behrens and Pulewka asphyxiated twelve cats with carbon monoxide. The respiratory movements and the blood pressure were recorded on a kymograph. The time intervals were 30 seconds. The arrow shows the shutting off of CO and the supply of air. The respiratory curve did not improve. It showed every 30 seconds a deep sigh and 8 to 9 very slight breaths. Death seemed to be inevitable. At this moment Alpha-Lobelin 0.002 g was injected. Within 1/4 minute 16 very deep breaths per 30 seconds were recorded. Blood pressure did not change. In all of these twelve cases Alpha-Lobelin successfully resuscitated.

As a matter of fact, the tracing shows that the depth of respiration had begun to increase and the blood pressure was not falling at the moment that the lobelin was injected and that the respiration continued to increase after the injection. The tracing shows no essential change in blood pressure. Behrens and Pulewka (*Klin Wchnschr* 3 1677 [Sept 9] 1924) state that they used Alpha-Lobelin on twelve cats, that invariably there was excitation of respiration, that as a rule the cats were saved and that only in those cases in which the carbon monoxide had been continued so long that the blood pressure had fallen low did the animals die. [Cf last sentence of Reichle's just quoted.] In a personal communication Reichle stated that he used the term 'resuscitated' not with regard to the ultimate recovery of the animals but with reference to the respiration. He further stated that further experience has necessitated considerable modification of his earlier views and that he regrets the continued circulation by the agents, of his now antiquated review, which was done without his knowledge. He now holds that the statement "It distinguishes itself by being void of all stimulation of the vomiting center such as the crude drug has" has now been disproved. The foregoing is cited merely as evidence that much found in this book is of the uncritically "promotional" type.

The first article in the blue-covered book, which is unsigned and is presumably made by the manufacturer, states that massive doses were not fatal in animal experiments, that the absence of toxicity is due to the fact that Alpha-Lobelin is soluble only in low concentrations. The Council's referee believes this statement to be dangerous in view of the fact that Alpha-Lobelin is recommended for intravenous injection. It is recommended directly or by inference for the treatment of carbon monoxide poisoning, but it is almost certain that Alpha-Lobelin is of much less value in severe poisoning with

carbon monoxide than is oxygen, and the referee believes such recommendations to be distinctly dangerous. One of the leaflets is entitled 'Life-Saving Action of Lobelin Ingelheim in Pneumonia' a misleading and dangerous statement. Even more misleading are several of the leaflets devoted to the report of a case of severe isol poisoning cured by Lobelin Ingelheim. Peters states

Based upon the pharmacologic findings of exhaustive tests Alpha-Lobelin is clearly indicated in all forms of central respiratory depression either partial or complete.

This is so obviously misleading and dangerous that it does not call for comment. The advertising contains the statement many times repeated that Alpha-Lobelin in contrast to the older amorphous lobelin is not emetic. The following quotation is from Reichle (page 23, blue covered book)

It distinguishes itself by being void [sic] of all stimulation of the vomiting center—such as the crude drug notoriously has—and by its specific and extremely powerful and reliable action upon the respiratory center.

Attention is called to the later statement of Reichle quoted above. The advertising is based largely on the investigation of Wieland but it is less conservative than Wieland and Mayer (*Arch f exper Path u Pharmacol* 92 195 1922), who state that while lobelin influences the morphine depression of the respiratory center easily it influences that of urethane less, and that of chloral hydrate much less (*verhältnismässig schwer*). Their experiments were conducted on rabbits, and they state that large doses cause paralysis of the respiratory center, that the highest doses cause tonic clonic convulsions of cerebral origin but that this is induced only by intravenous injection.

Dreser (*Arch f exper Path u Pharmacol* 26 237, 1890) states that alkaloid lobelin is the only active constituent of *lobelia inflata* that it causes paralysis of respiration in mammals that it abolishes voluntary movement in the frog while it increases reflex excitability, that it paralyzes the vagi in the frog heart like nicotine, that the most prominent action in the mammal is a powerful stimulation of respiration, that the depth and rate of respiration and the force of the muscles innervated from the respiratory center increase. Dreser calls attention to the use of lobelia as an emetic in the United States.

Edmunds (*Am J Physiol* 11 79, 1904) states with reference to lobelin

In warm blooded animals (cats and dogs) the main effects of small doses are due to the powerful emetic action of the drug most of the symptoms being secondary to the vomiting which is due to action on the medulla. In larger doses muscular twitchings are followed by tonic convulsions and death. The drug is a powerful respiratory stimulant in small doses and in large quantities causes death by paralyzing the respiratory center.

Norris and Weiss (*J Pharmacol & Exper Therap* 31 43 [May] 1927) studied the actions of Alpha-Lobelin as a respiratory stimulant in (a) morphine poisoning, (b) poisoning by derivatives of barbituric acid and chloral, (c) poisoning by combination of morphine and of barbituric acid derivatives (d) carbon monoxide poisoning, (e) increased intracranial pressure.

In contradiction to Wieland and Mayer, Norris and Weiss state that Alpha-Lobelin produces effects in unanesthetized rabbits and cats similar to those observed by Edmunds with amorphous lobelin. They report that the fatal dose for the rabbit is about 10 mg per kilogram by the vein, that intravenous doses of 2 mg per kilogram cause clonic convulsions followed by rapid and shallow breathing, that normal animals are more sensitive to the stimulating effect of Alpha-Lobelin than those with respiratory depression, and that when the respiration is depressed other functions related to the medullary centers are also disturbed and the effect of the drug may be altered. They observed its effects on twenty-one men, including themselves. They state in the summary and conclusions that the pharmacologic properties of Alpha-Lobelin are essentially similar to those of the amorphous impure alkaloids or extracts of *lobelia inflata*, that the emetic respiratory and vasomotor actions of Alpha-Lobelin are similar to those of nicotine, that the mixture of carbon dioxide and oxygen is a more efficient and a safer respiratory stimulant than Alpha-Lobelin.

In marked contrast to the tone of the greater part of the literature previously cited is a paper by Wilson on the treat-

ment of asphyxia neonatorum by the injection of Alpha-Lobelin into the umbilical vein (A Preliminary Report *Am J Obst & Gynec* 16 379 [Sept.] 1928) Wilson states that a larger number of cases are necessary before definite conclusions can be drawn but that this preliminary report is presented in order to draw attention to the use of this drug in the manner which he describes. Wilson cites various authors who have observed spasms which, however, were attributed to impurities the Council's referee points out that Walbaum (*Arch f exper Path u Pharmacol* 116 1 1926) reported that two specimens of Lobelin-Ingelheim examined by himself caused strychnine-like convulsions but that twenty eight other specimens did not. Wilson's article is conservative and the referee believes that he has shown that Alpha-Lobelin is sometimes useful in asphyxia neonatorum. The referee has been informed that Alpha-Lobelin is now used widely for stimulating the respiration of the new-born.

It has long been known that moderate doses of lobelin like nicotine, stimulate respiration markedly. In fact, extraordinarily small doses of nicotine cause increased respiration in the frog, but neither nicotine nor lobelin has established itself as a respiratory stimulant in a greater number of cases, in which carbon dioxide and oxygen are now employed.

In accordance with the foregoing discussion and the referee's recommendation based thereon the Council declared Alpha-Lobelin unacceptable for New and Nonofficial Remedies because it is marketed with unwarranted therapeutic claims.

Committee on Foods

REPORTS OF THE COMMITTEE

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMOTION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTRIG Secretary

QUAKER BRAND PUFFED RICE

Manufacturer—The Quaker Oats Company, Chicago

Description—Ready-to eat cooked and puffed polished rice

Manufacture—Polished whole rice kernels are cooked and steamed in a closed vessel called a "gun." When the desired pressure has been reached, the lock that seals the gun is quickly withdrawn and the door is forced open by the internal steam pressure. The quick release of pressure causes a sudden conversion into vapor of the moisture within the rice and puffs it to light, porous grains. The puffed rice is screened dried to 2 per cent moisture content, and packed in paraffin bags in cartons.

Analysis (submitted by manufacturer) —		per cent
Moisture		2.0
Ash		0.4
Fat (ether extraction method)		0.4
Protein (N \times 6.25)		6.2
Crude fiber		0.5
Carbohydrates other than crude fiber (by difference)		90.5

Calories—3.9 per gram 111 per ounce

Claims of Manufacturer—The rice is steam exploded to eight times normal size.

BETTY JANE FLOUR (BLEACHED)

Manufacturer—The Robinson Milling Company, Salina, Kan.

Description—Hard winter wheat patent flour bleached

Manufacture—Selected hard winter wheat is cleaned, scoured, tempered and milled by essentially the same procedure as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended, and bleached with nitrogen trichloride (one seventh ounce per 196 pounds) and with a mixture of benzoyl peroxide and calcium phosphate (one half ounce per 196 pounds).

Claims of Manufacturer—For general baking

BABY RUTH LEMON, LIME AND ORANGE DROPS

(ADDED COLOR AND ACID)

Manufacturer—The Curtiss Candy Company, Chicago

Description—Confection drops containing sucrose, corn syrup, tartaric acid, lemon, orange or lime oils and colors certified by the United States Department of Agriculture.

Manufacture—The sugar and corn syrup are cooked together under reduced pressure and admixed with the acid and the respective flavors and colors. The entire mass is thoroughly pulled and worked until a uniform distribution of the color is obtained. The batch is placed in a spinning machine and spun directly into a "drop" or "stamping" machine, where the individual drops are turned out, cooled in a cooling tunnel, and automatically packaged.

Analysis (submitted by manufacturer) —		per cent

- 4 Stokes Milling Company
- 5 Minneapolis Milling Company
- 6 Commander Milling Company
- 7 Buffalo Flour Mills Corporation

Subsidiaries of the Commander-Larabee Corporation, Minneapolis

Description—Hard spring wheat patent flour, bleached

Manufacture—Selected hard spring wheat is cleaned, washed, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended and bleached with a mixture of benzoyl peroxide and calcium phosphate (three-fourths ounce per 196 pounds).

Claims of Manufacturer—For commercial baking and family use.

LUXURY BREAD WITH SUNSHINE VITAMIN D

Manufacturer—Spaulding Bakeries, Scranton, Pa.

Description—A white bread prepared by the sponge dough method containing an added special nutrient vitamin D equivalent to the vitamin D of three teaspoonfuls of standard cod liver oil for each 24 ounces of baked bread (140 vitamin D units defined by the Council on Pharmacy and Chemistry, New and Nonofficial Remedies, 1932, p. 424) and manufactured under license granted by the General Baking Company, the same as Spaulding's Sunshine Vitamin D Bread (THE JOURNAL, March 12, 1932, p. 888).

WINFIELD SUPREME BRAND UNSWEETENED EVAPORATED MILK

Pacler—The Page Milk Company, Merrill, Wis.
Distributor—Winfield Wholesale Grocery Company, Wichita, Winfield, Kan.

Description—Canned unsweetened, evaporated milk, the same as "Page Evaporated Milk Sterilized Unsweetened" (THE JOURNAL, May 30, 1931, p. 1872).

DELAYED WOUND HEALING

Soon after the discovery of insulin and the demonstration of its specific value in the management of diabetes, recommendations as to the value of the product in other fields of therapeutics began to appear. Macleod observed long ago that, in the normal laboratory animal at least, the endogenous supply of insulin seems regularly to be at an optimum. This fact would tend to discourage the use of insulin in nondiabetic conditions. In the course of time, however, the possibilities of occasional advantage from the use of the hormone have been brought to light. A few months ago, Williams and Dick¹ of Chicago recorded their experience showing that glycosuria occurs in a large proportion of persons with acute infectious disease. The largest average amount of dextrose was excreted by the patients with influenza and miscellaneous acute infections. This glycosuria is accompanied by a lower carbohydrate tolerance as shown by dextrose tolerance tests and blood sugar curves both in acute infectious diseases and in experimental infections in animals. Administration of insulin improves the dextrose tolerance in acute infections. According to Williams and Dick, the action of insulin in improving the carbohydrate tolerance in acute infections is analogous to its similar action in diabetes mellitus. In many instances the severity of the disease and the degree of reduction of tolerance could be correlated, and in patients having one contagious disease following another there was marked reduction of tolerance. This suggests a probable important factor in the etiology of diabetes. The recovery of tolerance following injury by infection is explained by immunity to the infecting organism and by regeneration of the islets of Langerhans. The latter occurrence has been demonstrated in cases of diabetes, in which the tolerance of the patient has been improved.

Comparable lack of dextrose tolerance in persons who might not ordinarily be classed as diabetic has more

recently been reported by Rabinowitch² of the Montreal General Hospital. Recalling the well known fact that the surgical wounds tend to heal slowly or not at all in the patient with uncontrolled diabetes, he has studied the dextrose tolerance of patients exhibiting instances of the slow healing of wounds. For example, in the case of so-called birth trauma a high incidence of abnormality in sugar tolerance was observed. Although wounds failed to heal at the normal rate prior to treatment, wounds would heal at the normal rate with diet and insulin therapy. Infection was present in some of these cases, but other usual conditions that might explain impaired healing of tissue were excluded.

The experience at Montreal indicates that the routine study of carbohydrate tolerance in cases of slow healing of wounds may be well repaid in many instances. Good results often follow the appropriate insulin therapy. Rabinowitch asks whether it is possible that many of the patients of the sort designated have diabetes, that glycosuria is not observed because the blood sugars are below the renal threshold for dextrose, and that the disease becomes obvious only when these persons are exposed to some injury or infection that causes further loss of carbohydrate tolerance. Longer experience will give a more decisive answer. It is fortunate to have the attention of clinicians drawn anew to the association between impaired carbohydrate metabolism and delayed healing.

THE PERIODIC PHYSICAL EXAMINATION IN YOUTH

The protection of health through periodic physical examination, like international disarmament, has been accepted in principle with but little practical result. The plan was first proposed in 1861 by Dr. Horace Dobell, whose recommendations were ignored. It was again suggested in 1901 by Dr. George M. Gould. The effort toward popularization was officially endorsed by the American Medical Association in 1922, but commercial exploitation had begun before 1917. State and county medical societies, public health officials and insurance companies have done their utmost, yet the gain in popular favor represented by increased utilization is slight. For the most part, the American people have not translated their acceptance of the idea into action.

Perhaps one of the reasons why the examination of apparently healthy persons as a prophylactic measure has not been more popular is that too much emphasis has been placed on life extension and not enough on life enrichment. Certainly, there is little good evidence that periodic examination will appreciably lengthen the life span. There are too many factors involved in longevity, heredity among others, which cannot be influenced by such a prophylactic measure. Moreover, too much emphasis has been laid on the examination of the appar-

² Rabinowitch I. M. Simultaneous Respiratory Exchange and Blood Sugar Time Curves Obtained in Apparently Nondiabetic Patients with Nonhealing Wounds. Arch. Surg. 26: 697 (April) 1933.

ently healthy adult and not enough on the necessity for beginning health supervision at the beginning of life. In middle life, little can be expected, perhaps, aside from a discovery of harm already done, and possibly a tardy economy in the expenditure of remaining resources of health.

If the periodic health examination is to be popularized among young persons as a worthwhile practice for the enrichment of life, it must be offered on a different basis. The conception of future health makes little or no appeal to youths of high school or college age, who as a rule have abundant health and cannot be induced to worry about losing it. The child, still under closer control of parents, is more likely to have health supervision. The adult, sobered by responsibility for home and family, will protect his health if he is intelligent, and may be expected to respond to an appeal based on reason.

The Boy Scouts of America have a phrase in their oath, "a scout keeps himself physically strong and mentally awake." Among their merit badges are some pertaining to personal health, public health and first aid, to say nothing of the numerous others which have an incidental and therefore relatively painless health significance in that they encourage outdoor life and physical fitness indirectly. Among the principles of the Camp Fire Girls is an alliterative adjuration, "Hold on to Health," and this is given practical expression through the encouragement of activities that especially promote the improvement of physical efficiency.¹ The 4-H—Head, Heart, Hands and Health—Movement is another which is encouraging the interest of young persons in health through an immediate and practical approach. These, of course, are not all, they are cited merely as examples of how the conception of periodic health inventories is being translated—as it must be if it is to succeed—into terms that give the idea an immediate applicability and attractiveness.

Blanks for the recording of the periodic health examination have been prepared by the American Medical Association² and by state and county medical societies. A blank just issued by the Camp Fire Girls organization drops all formality. It talks about "family tree" instead of "family medical history," gaily and intimately records the facts about "grandpa" and "grandma" on both sides of the family, and interlards the dull recital with gay little line drawings in the well known "match-man" manner to illustrate brothers and sisters living or dead. Moonfaces with appropriate curves, up or down as the case may be, illustrate the individual's status as "very healthy," "pretty healthy," "fair" or "poor." Information about the teeth is recorded thus: "None are dead and none need filling, for my diet is right and I keep them clean and the dentist does the rest," or, "I'm sorry, but they DO

need." Enough has been cited to show the spirit of this record. The thing has an urge for the young girl, who naturally doesn't like the apologetic "I'm sorry, but." She is likely to go and do something about it, or, as the psychologist would say, she is motivated to action.

This interest of lay organizations in matters pertaining to health is hopeful. They need medical guidance, in order that their activities may be constructive. False hopes need not be raised. Erroneous impressions should not be fixed in minds from which they must later be eradicated. Available evidence indicates that large numbers of county medical societies are cooperating with movements of this character. Many lay organizations have national advisory committees on which the American Medical Association has representation. Through close cooperation between the medical profession and the public on a national, state and local basis will come the soundest progress toward better public health.

ROENTGENOGRAMS THE PROPERTY OF THE PHYSICIAN

Roentgenograms made for a physician or a dentist, to assist in diagnosis and treatment, are not chattels in the sense that they can be bought and sold but are a part of the records of the case. In the absence of an agreement to the contrary, they belong to the physician or the dentist. This is the gist of the decision of the Municipal Court of Dayton, Ohio, Irwin W. Rohlf, acting judge, in *Leas v. Otto*, Aug. 4, 1932. The case¹ is the third in which a trial court has held that a roentgenogram made for the purposes of diagnosis and treatment does not belong to the patient unless there is an express agreement to that effect. As far as is known, however, no appellate court of last resort has passed on the question.

The plaintiff in the present case, a dentist, advised that a roentgenogram be made of the teeth of the defendant's wife. This was done, and a charge of \$10 was placed on the books. At a second visit, the dentist stated his diagnosis and advised as to the work that he recommended be done, and a charge of \$5 was made for this service. The defendant decided not to have the proposed work done but he demanded that the roentgenogram be given to him. The dentist refused. The patient's husband paid the \$5 charged for the diagnosis and advice but refused to pay for the taking of the roentgenogram. The dentist thereupon sued to recover the amount due. The facts were admitted, the only question being whether the dentist or his patient's husband, who was liable for the cost of dental services for the wife, owned the roentgenogram. Judgment was rendered in favor of the plaintiff-dentist, following

¹ Hold on to Health J. Health & Physical Education December, 1932

² Blanks for recording periodic physical examinations are available at 5 cents each postpaid, from the American Medical Association

¹ See also *Hurley Hospital v. Gage*, Circuit Court of Genesee County, Mich. April 21 1931. J. A. M. A. 97:1542 (Nov. 21) 1931. *Thoecher v. Barnum and Pinkham*, Circuit Court of Ingham County Mich. April 4 1932, Am. J. Roentgenol. 27:906 (June) 1932.

an opinion that cannot be stated better than in the court's own words

The determination of this question involves the question of whether the x-ray film is a chattel subject to be bought and sold on the same basis as any other chattel. The court is of the opinion that an x-ray film is not a chattel in the sense that it can be bought and sold.

When a dental surgeon or a physician makes an x-ray of a patient he is required to have certain equipment in his office and to that end he purchases the x-ray machine itself and in the making of an x-ray film for a patient he pays for the material that goes into the making of said x-ray film or picture, and when said film or picture is produced it becomes a part of the record of that particular case and a part of the equipment of his office, said x-ray film or picture is of service and value only to the dental surgeon or physician who has knowledge and training in diagnosing the particular case and is a part of the record of that particular case and of value in giving said dental surgeon or physician enlightenment in the treatment of said case.

In the making and reproduction of an x-ray film for a patient the dental surgeon or physician sells and the patient pays for, not the material that goes into the x-ray film but for knowledge and experience.

It is a fundamental proposition that the law will not make an implied agreement to transfer ownership of an x-ray film or picture from the person producing it to the patient in the absence of an express agreement to the contrary.

In this case there is no testimony that there was an express agreement to transfer ownership of the x-ray film from the plaintiff to the defendant. The plaintiff testified that it is customary that such films be retained by the person who has taken them. The court is of the opinion that the retention of said films by the person taking them is necessary as a part of his record concerning the case, retained on the same basis and on the same theory that a surgeon retains his temperature chart that he has made, or other record concerning the diagnosis or treatment of a case, and that as a matter of law it must be said that where x-ray pictures are taken under circumstances such as they were taken by the plaintiff in this case, there is no implied undertaking to turn those films over to the patient.

The court is further of the opinion that the protection of the person taking said films depends largely on the proper preservation of the same and such films should remain with said dental surgeon or physician. The interpretation is the all-important thing in connection with an x-ray examination. The film itself is simply the basis of the interpretation.

Current Comment

POSITIVE FACTORS IN THYROID HYPERPLASIA

The pathologic manifestations of endemic goiter are at present attributed almost universally to a diminished supply of iodine to the affected person. On this basis the malady may properly be classified as a deficiency disease. Marine, who has made extensive studies in this field of investigation, believes that the morbid anatomy of endemic goiter involves, first, a diminished iodine store and, secondly, a period of stimulation with hyperplasia.¹ There are several well known investigators who have repeatedly insisted that positive factors play an important part in thyroid hyperplasia, and that they are quite as important as any shortage in the iodine intake. Indeed, one writer has argued that atrophy of the thyroid should result from a lessened supply of iodine, as this element tends to stimulate the

gland. Two years ago, Hellwig² expressed the view that an increased intake of calcium chloride represents a positive agent, which, if presented simultaneously with a shortage of iodine, will bring about thyroid hyperplasia. The problem should, of course, be readily subject to experimental investigation on laboratory animals. The ubiquitousness of iodine in effective traces in nongitrous areas makes experiments difficult and uncertain in their outcome. Nevertheless, a study carried out at the College of Physicians and Surgeons in New York by Hibbard³ on rodents tends to support the existence of positive as well as deficiency factors in the development of thyroid hyperplasias. Albino rats fed on a diet low in iodine in a relatively nonendemic region failed to have thyroid hyperplasia. On the other hand, administration of calcium chloride, combined with a diet low in iodine, produced a definite thyroid hyperplasia in a large percentage of the experimental animals. Hyperplasia was not observed in experimental rats fed on a diet high in calcium lactate and low in iodine. Definite changes in the thyroid gland, similar to those obtained by a diet high in calcium chloride and low in iodine, were found in rats fed on a diet high in sodium chloride and low in iodine. Hibbard asserts that, although his experiments are not yet entirely convincing, they tend to indicate that the positive element was the chlorine and not the calcium ion. Whether this action is specific for chlorine or may occur with other halogens is not absolutely proved in this study.

PATHOGENICITY OF VARIANTS OF B TUBERCULOSIS

During the last decade it has become increasingly evident that pure cultures of pathogenic bacteria may "dissociate," "mutate" or "degenerate" into two or more morphologic or antigenic "variants," "strains" or "involution forms," and that somewhat similar microbial "phases," "life cycles" or "transformations" are demonstrable during the course of natural infections. Thus far, studies of microbial "plasticity" have been largely morphologic. Working with a well known strain of the avian tubercle bacillus, Drs. Winn and Petroff⁴ of the Trudeau Sanatorium readily obtained three relatively stable test-tube "dissociates," easily differentiated from one another by differences in colony structure. These variants they designate as the smooth (S), rough (R), and flat-smooth (FS) types, to which they added a fourth, or chromogenic (Ch), variant, obtained by subjecting an S culture to a relatively high temperature. Sixty-one young fowls of approximately the same size and age were inoculated intravenously with graded doses of these four "dissociates." Detailed clinical histories were kept, including repeated differential blood counts, followed by careful histologic studies of all inoculated birds. Their general conclusion is that the leukocytic response to S and FS infections is of the acute tuberculosis type, while the response to R and Ch infections is characteristic of

² Hellwig C. A. Iodine Deficiency and Goiter. Arch. Path. 11: 709 (May) 1931.

³ Hibbard J. S. Experimental Thyroid Hyperplasia. Arch. Surg. 26: 648 (April) 1933.

⁴ Winn W. A. and Petroff S. A. J. Exper. Med. 57: 239 (Feb) 1933.

chronic healing tuberculosis The individual tubercles formed by the S infection were found to be of the acute, or "toxic," type The FS tubercle was of the less acute, foreign body type. The R and Ch tubercles were "relatively benign" The differences were clear cut, in spite of the tendency of the four variants to be sometimes unstable in vivo, a characteristic influencing both the advancement and the retrogression of the experimental lesions Dissociated variants of the human and bovine strains of *Bacillus tuberculosis* are much less stable than those of the selected avian culture

Medical Economics

THE COLLECTION PROBLEM

The collection problem is peculiarly difficult in the medical field Ethics, professional tradition and present practices have introduced so large an element of philanthropy that debts for medical service seem to have lost the sharp sense of obligation that distinguishes commercial debts The imperative necessity of preserving close personal relations between patient and physician increases this effect

Business sagacity proverbially is seldom associated with science and art the good physician is often a poor collector Attempts to place the handling of delinquent accounts with commercial collectors only aggravates the whole situation, often defrauding the creditor and enraging the debtor, and profiting only the unscrupulous collection agency

Estimates of the losses of physicians through failure to collect vary from 15 to 50 per cent of charges Since the estimate of the amount paid to physicians is over a billion dollars annually it follows that probably no less than \$300,000,000 is lost each year through inability to collect payment for work done.

As a first step in a study of the collection problem a questionnaire was sent to all secretaries of county medical societies The replies differed distinctly from those received to other questionnaires Usually replies differ widely, reflecting divergent opinions, local conditions, and so on, but this time the replies were so nearly unanimous that it became evident that little would be gained by analyzing the total of nearly 2,000 questionnaires Examination of a sufficiently large sample to be representative showed that about one half of the physicians utilized the services of general collection agencies

The second question asked for "a list of the collection agencies that have been fair in their dealings and have given general satisfaction to the majority of your local society members" Practically every agency listed in reply to this question was a local one Scarcely a name of a general national agency was mentioned

The third question asked for a listing of "those collection agencies that have been found to be tricky, inequitable and unsatisfactory to your members who have used them" The most common reply was "All" or "Every one," although a large number were specifically named

The replies to these three questions demonstrate that while about one half of the physicians in the country have used collection agencies, the only ones that have been satisfactory have been local organizations, where personal relations and supervision are possible This means further that a large percentage of the physicians have had dealings with "tricky, inequitable and unsatisfactory" agencies

A number of replies to the second question endorsed, sometimes with enthusiastic emphasis, agencies operated under the direct supervision of the physicians themselves This suggested the probability that these physicians were at least approaching a solution of this vexed problem of collections

Special letters were sent to those secretaries of county medical societies who reported the existence of such professionally controlled agencies Sufficient replies were received to indicate that these societies seemed to be pioneering the way to a greatly

improved method of handling physicians' accounts It is believed that a study of the methods used will be helpful to physicians in other localities

Ten of the organizations reporting the details of their form and operation have been in existence for a sufficiently long time to speak from experience as to the success of their methods. The following descriptions of the workings of some examples of such organizations are summarized from letters and other information furnished by the secretaries of the county medical societies or from the managers of the organizations

THE PHYSICIANS AND DENTISTS BUSINESS BUREAU OF TACOMA, WASH

The Physicians and Dentists Business Bureau of Tacoma, Wash., is a corporation organized not for profit, with no capital and no stock, whose owners are the members

The bureau had its origin in a committee appointed by the president of the county society to investigate the possibility for the formation of such a bureau The committee worked out a number of plans, reported to the society at a special meeting, and was authorized to proceed to form a corporation to engage in four general activities (1) collection of past due accounts, (2) maintenance of credit statistics, (3) operation of telephone exchange and (4) public relations A law manager was employed to organize the company and set up a going concern Space was rented in the Medical Arts Building, and membership solicited A fee of \$5 was levied for admission into the corporation This might be called an initiation fee. Any member of the medical or dental societies in good standing is eligible to be a member of the bureau on payment of this fee The fee is not annual but is levied only once, at the time of entering into membership

It is important in the establishment of bureaus of this nature to combine as many services as is practicable under one staff and one organization in order that the resulting economies in operation and overhead will enable the bureau to render its services in competition with other commercial organizations It has been the experience of this bureau that the operation of the telephone exchange and nurses' registry can be associated with credit and collection service with a substantial saving over the probable cost of operating these organizations separately A considerable part of the clerical work of both organizations is done by the nurses at the exchange

The collection department employs a collection supervisor, an accountant who also handles the accounting for the exchange, a collector and a tracing department

The charges for collection are as follows accounts under \$10 or over one year old, 33⅓ per cent, under one year, 25 per cent, six months, 20 per cent, three months, 15 per cent

Present economic conditions have made it impossible to collect many accounts without unduly burdening many patients

When satisfactory evidence is offered that the patient cannot meet the obligation and is conscientiously endeavoring to do so, an application for an extension of credit is used The application form is an acknowledgment of the account and when properly filled out, is a financial statement of the debtor's condition and a promissory note to pay This is now resulting in the collection of accounts in proportion of about \$1 in cash collected to \$7.50 in notes signed. These credit application blanks are reviewed at periodic intervals, the frequency of which is determined by the individual account, and further treatment is given them as soon as necessary

The bureau employs an attorney, who renders any services requested by the bureau and advises the bureau and consults with its manager in all cases involving the law The attorney's remuneration is received from the fees that are allowed by the court in which judgment is obtained on accounts

The collection department has been able to operate efficiently While the present extreme depression of credit and the country-wide unemployment situation make it impossible to appraise the exact collection value of the bureau, nevertheless the bureau has succeeded in collecting accounts on a basis which compares favorably with its commercial competitors in this area The average commercial rate for collections in this district is now 48 per cent and the rates of the bureau are substantially less than this amount. The bureau cannot operate on its present rate schedule as a single unit and in present conditions except by combining the various activities of the bureau under one staff

MEDICAL AND DENTAL CREDIT ASSOCIATION,
NORFOLK, VA.

The Medical and Dental Credit Association, Norfolk, Va., was organized and began operations in January, 1930 with about sixty members. At that time a membership fee of \$10 was charged and 33 1/3 per cent on accounts collected by the association. The board of directors is elected from the membership which is restricted to ethical members of the medical and dental professions.

The first year, approximately \$24,000 was collected and the total, up to the present time, is approximately \$80,000 for a membership which now exceeds 150. The membership fee has been reduced to \$1 and the rates have been changed to conform with the prevailing rates charged by commercial agencies.

The amount that was collected directly is small in comparison to the amount received by the doctor in his own office through the influence exerted by the association.

At regular intervals a complete report of all delinquent accounts handled through the office is furnished in printed form and distributed to the membership, together with individual credit reports as requested by the members. The association is meeting with approval and is gaining membership continually. The accounts handled are investigated carefully and if they are deserving of charity the doctor is notified if debtors are able to pay for professional services steps are taken to force payment immediately. Debtors are also assisted in financing their accounts with the doctor.

PHYSICIANS' BUSINESS BUREAU, MEMPHIS, TENN.

The Physicians' Business Bureau, Memphis, Tenn. is not operated directly by the medical society but by a separate corporation owned and controlled entirely by members of the society. This corporation was organized in 1919 and began operating as a collection and rating bureau in May, 1922. Since then it has handled the accounts of physicians, dentists and hospitals, has collected a little over a million dollars, and has disposed of twice that amount of "uncollectable" accounts.

At first a small membership fee was charged but it was found that the bureau could operate solely on a commission basis, which averages about 22 per cent. Business was begun with only \$900 capital stock paid into the organization. The large volume of business was obtained without a loss to any member and without any failures to turn over the money collected which is so common with commercial agencies. There is a settlement with the doctors every month when all amounts due are paid, less commissions for collections.

Out of the income that has been derived from commissions have been paid all expenses and a comfortable surplus set aside, which is now carrying the Bureau over a period that would have been embarrassing if not prepared for.

The question of opening a finance department to take care of patients that are entitled to loans to pay their medical expenses is being considered. If such a department is opened it will be under the direct supervision of a board of directors, and all of the stock will remain in the hands of the local medical profession.

QUEEN'S MEDICAL BUSINESS BUREAU, INC., BROOKLYN

The Queen's Medical Business Bureau, Inc. of Brooklyn, the stock of which is owned 100 per cent by the county medical society, is a distinct corporation although the directors are trustees of the county medical society.

This business bureau supervises the use of space in the county medical building securing compensation proportionate to the time it is used by organizations allied in their activities to the county medical society. It also maintains a nurses registry under the supervision of a graduate nurse.

The collection bureau has been in operation for approximately two years. It has never made money nor has it during the last year been a source of expense. It is under a lay manager, who has a year's contract with the business bureau and any profit accruing goes into his pocket. This department has been of service to the members of the county society and has brought satisfactory results to certain members.

It has made collections of delinquent accounts not only for physicians but also for some of the private hospitals in the county. The rate is 50 per cent up to \$10 and 25 per cent thereafter.

On cases referred to a lawyer for the collection of the debt the charge is 35 per cent plus a small additional fee for serving of papers, and the like. Twenty-four hour credit reports on patients or individuals are also furnished on request. The delinquent is first sent several follow-up letters. If these are not effective, a collector, who is maintained by the department on a commission basis, is sent. If the collector is unable to produce results, these accounts are sent to a lawyer, who collects through correspondence or specific court action.

The greatest difficulty in the management of this part of the business bureau activity seems to be in securing reliable managers.

DETROIT PHYSICIANS' BUSINESS BUREAU

The Wayne County Medical Society has maintained a physicians' business bureau in Detroit since 1915. The Detroit Physicians' Business Bureau was organized as a cooperative collection service for the members and to act as a bureau for credit information. It is not incorporated. Originally, the society gave financial assistance to the bureau during the period of its "organization pains." However, it has been self-supporting for years and at present is a source of some small revenue to the society.

The bureau has its own business office, which is located for the convenience of its members, in the Wayne County Medical Society Building. It is under the management of a full time layman who is supervised by a committee of society physicians appointed by the president. The society has a contract whereby it is relieved of all financial responsibility. The special committee, or board of control, acts as arbitrator in any disputes between the bureau and the physicians and it also audits the books annually. One per cent of the gross collections is turned over to the society by the business manager as rental of the name "Detroit Physicians' Business Bureau," which is the property of the Wayne County Medical Society.

There is no monthly membership fee for the business bureau service. The physicians pay only a percentage on the money collected for them.

The bureau offers three services to every member: first, a delinquent account letter service, whereby a series of letters is mailed by the bureau to slow-pay patients to aid the doctor's collections (the cost is 5 cents for each letter); second, a collection service, which is a dependable help to the physician who wishes to have his older accounts adjusted or financed through the medium of a conscientious agency; third, the help of "the physician's bookkeeper" for doctors who desire an expert bookkeeper to keep monthly accounts, pay bills and collect current fees.

The official sponsorship and supervision of the county medical society are necessary to make a success of a cooperative bureau. If it is an integral part of the society's activity, the physician can place his confidence in it. This means more clients for the bureau, a proportionate decrease in overhead, and more efficiency at a lesser price. Again, more satisfactory results to both physician and patient may be expected from the use of a local collection agency over which some influence and control can be exercised.

Two definite benefits result from the presence of an official medical bureau. 1. Physicians refer their claims to the third party (the agency) at an earlier age, which prevents rapid deterioration of accounts. 2. "Nation-wide" agencies and "gymps" of all varieties are lessened as physicians prefer to place their confidence in their own bureau, thus thousands of dollars are annually saved the individual practitioner of medicine.

The bureau has successfully collected about one third of the accounts received.

PHYSICIANS' CREDIT EXCHANGE, CHARLOTTE, N. C.

The Physicians' Credit Exchange was established Aug. 1, 1931, as a means of assisting the local medical library, but has since grown. Membership in this exchange includes membership in (1) the Mecklenburg County Medical Society, (2) the Medical Society of the State of North Carolina, (3) the Charlotte Medical Library Association, (4) the Merchants Association, (5) the Physicians' Credit Bureau, (6) the Physicians' Collection Agency, and (7) the local Doctors' Telephone Exchange.

The exchange has a group membership in the local merchants association. Through this, credit ratings on any person

in the community may be obtained together with the services of their collection department. Such a group membership is obtained for much less than individual membership would cost the individual doctors

The credit bureau consists of excellent files of names submitted by the local doctors to the secretary of the exchange. These names make up a list of delinquents, cross indexed, and information may be secured promptly. Additional information may be secured from the Merchants Association

The collection agency is a new feature and has scarcely had time to determine its real value. At present most of the accounts being submitted for collection are old and worthless. However many of the members have collected accounts which were considered as absolutely no good.

All of these services and memberships are secured for the rate of \$5 a month. About 75 out of a total of 115 physicians of the city are members. This gives an annual income of about \$4,500 which is more than sufficient to maintain the exchange and all its departments

PHYSICIANS' AND DENTISTS' CREDIT BUREAU, RICHMOND, VA.

The Physicians' and Dentists' Credit Bureau Richmond, Va., is owned and operated by the doctors and dentists. It furnishes information and handles collections for clients on a 25 and 50 per cent contingent basis, makes personal calls on debtors, and tries to collect the accounts in an amicable way if possible. However if not successful, a legal department with a competent practicing attorney in charge proceeds by legal action if necessary, to protect the clients interests. At this time there is a clientele of 180 doctors and dentists

MEDICAL-DENTAL HEADQUARTERS, SALEM, ORE

About three years ago, the local medical society at Salem, Ore., organized a bureau called the Medical-Dental Headquarters. Its purpose was to act as an information bureau, to disseminate health information to the public and to provide an organization of physicians which might function in any manner along economic lines. The establishment of the collection bureau was incidental and was taken as the only means whereby the bureau might be made self supporting

Since the bureau could serve only physicians of Salem and nearby towns funds were not taken from the local society for its establishment but doctors were solicited to join the Medical-Dental Headquarters and contribute money for its support. After the first year the headquarters has been self supporting from its collection service. It performs these services only for members and charges them a percentage for collections made.

Control of the headquarters is under a medical-dental committee appointed by the medical society, together with a similar committee appointed by the dental society. There are six doctors and three dentists on this committee.

MEDICAL BUSINESS BUREAU, MILWAUKEE

In June 1931, the Medical Business Bureau, Milwaukee, opened under the direction of the society. The agreement at that time was that the society would purchase all equipment and records and that the business manager would operate the bureau as though it were his own business, paying all overhead expenses and receiving all profits up to a certain point, at which the society would participate in the revenue derived.

The bureau started off auspiciously and did well. In June, 1932 several banks were closed and from then on there were many difficulties and the manager became definitely discouraged. However, the society felt that the bureau was doing such good work that it should be continued and when the manager asked to be released another was procured. The results have been pleasing to the society.

At present some 250 physicians out of 700 use this service. The policies of the bureau are under the direction of the Medical Business Bureau Committee, which through the executive secretary supervises the actual operation and the manager goes to it for assistance in straightening out difficulties.

UNSUCCESSFUL EXPERIMENTS

Not all the experiments have been successful, nor are the reasons for this always clear. The former manager of the

Nashville, Tenn., Physicians' and Dentists' Adjustment Bureau writes

Begin to advise that the bureau so far as collecting is concerned is out of business. The high rates of privilege tax forced us to close. We were required to pay \$900 per year and could not stand this. I was manager of this bureau and now I am managing a collection department for the professional men—doctors and dentists. In this way I am still collecting for the doctors and dentists but of course this does not have the same effect as being allowed to collect in the bureau's name however it is the best we could do.

In another city a bureau was organized and a secretary and attorney were employed, the former to be paid from money received by the county medical society from a contract for indigent care. The plan failed because

Several of the physicians who talked the loudest in favor of establishing the bureau have never turned in a single name of their delinquent debtors and I firmly believe they thought they would benefit by the other doctors making their patrons sore when they began to use some force. Then the business depression grew worse and the doctors have about quit handing in any names so I think we might write the word FINIS and call it a day.

The plan is good if they will all work and stick together but you know what happens when some will not cooperate it FAILS.

The following extracts from a letter from a manager of a less successful scheme show some of the difficulties of organization and operation

About two years ago in response to some agitation on the subject principally caused by several dishonest collection agencies preying upon the doctors of ——— this agency was formed. In order that no direct responsibility should fall upon the county society, it was placed under my direction as executive secretary.

Notwithstanding the fact that our collections were fully up to the average of other agencies there was not enough patronage from members of the society to make it a paying venture and it has continuously been in the red. As the demand for the service seems so small I have ceased advertising and we receive very few new accounts. It is here however if the members care to use it and it could be revived at any time.

We never furnished a credit rating to our members but have on file a large number of persons who are delinquents subject to the inspection of our members. We have never been asked for any credit information.

In some cases an affiliated organization is reported as giving satisfactory results, although in most cases there is actual control of these organizations by the county medical society, directly or indirectly. Some examples of these are given.

KANSAS CITY PROFESSIONAL BUREAU

The Wyandotte County Medical Society does not maintain its own collection bureau, but there is an organization known as the Kansas City Professional Bureau, which is very closely allied to the society with members from the society as directors. It charges a \$2 per month fee and 25 per cent on collections, which are personally supervised and is quite satisfactory. It also issues a bulletin monthly giving lists of all individuals owing physicians in the city and in addition has a move service whereby it gets all of the transfers and moves in the city. It also gives a list of the city court suits and the names of the individuals involved.

SAN JOAQUIN COUNTY, CALIF

The service in operation in San Joaquin County, Calif., is organized on a somewhat different basis and is described as follows by the secretary of the San Joaquin County Medical Society.

A gentleman with experience in collections and well known to members of the society presented a plan to the society and asked for their endorsement and support which was given him.

Members of the medical and dental societies were given an opportunity to enroll at a fee of \$3 per month they were to furnish whatever accounts they chose for collection on the additional percentage basis of 25 per cent on claims of \$10 and under and 10 per cent on all large claims. No claims were to be sued on without the permission of the owner of the claim.

Any member may have any information that is available as to the standing of patients whether they owe other physicians or dentists.

This bureau is a regular established licensed and bonded agency under the laws of the state of California and is so controlled and conducted. It makes regular monthly reports of all payments received and all other information that is of importance regarding a claim.

Our collection fees have been materially reduced the type of service is more in accordance with our desires and has given us an outlet for accounts that would not otherwise be given to the ordinary collector.

CONCLUSIONS

There are a few tentative generalizations that seem to be established by the experiments described. Control by the county medical society directly or indirectly appears desirable.

This can be obtained either by provisions for such control in the by-laws, by retaining ownership of the title of the collecting agency, or by confining membership in the agency to members in good standing of the professional organization.

The active cooperation of at least a majority of the county medical society should be assured before the plan is put in operation. One successful means of securing this is to ask a small membership fee at the beginning, which also assures the working capital required for the start.

Those plans seem to have succeeded best which charge approximately the same rates as commercial agencies and depend on an improved service, made possible by absence of any expense for soliciting accounts and increase of income through the prestige of professional connections to attract patronage. This enables the agency not only to be self-supporting and to accumulate sufficient surplus to carry it through a depression but also, when established perhaps to be a source of at least a small income to the county medical society.

If the collection agency is financially self-supporting it can offer other services, such as financing slow pay accounts and furnishing credit reports. There would appear to be some difficulty in finding lay managers who combine the requisite skill in collection methods with the attitude which the profession wishes to retain with the delinquent patients, yet this is absolutely essential to general satisfaction.

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday from 9:15 to 9:20 a. m., Chicago daylight saving time which is one hour faster than central standard time, over Station WBBM (770 kilocycles, or 389.4 meters).

The subjects for the week are as follows:

June 20. Vacation First Aid Kit.
June 22. Three Fingered Poison.

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9:45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

June 24. Whooping Cough.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Dr. Chandler Appointed Dean of Stanford Medical School—Dr. Loren Roscoe Chandler, assistant clinical professor of surgery, Stanford University School of Medicine, San Francisco, has been appointed dean of the school, succeeding the late Dr. William Ophuls. Dr. Chandler, who graduated from the medical school in 1923, has been associated with the department of surgery since that time. He is 38 years of age and a native of California. He is a member of the board of directors of the San Francisco County Medical Society.

Tribute to Dr. Soiland—Radiology for May has been dedicated to Dr. Albert Soiland, Los Angeles, in acknowledgment of his achievements in radiology and in recognition of his sixtieth birthday. Dr. Soiland was born in Stavanger, Norway. He graduated at the University of Southern California Medical School, Los Angeles, in 1900, where, in 1904, he established a department of radiology. He was the founder of the American College of Radiology and at present is a member of the House of Delegates of the American Medical Association. He will represent the latter at the fourth International Radiological Congress, to be held in Zurich, Switzerland, in 1934. Dr. Soiland was a sponsor of the plan to

establish the Section on Radiology of the American Medical Association, and in 1926 was made its chairman.

CONNECTICUT

Dr. d'Herelle Resigns—Dr. Felix d'Herelle has resigned as professor of bacteriology at Yale University School of Medicine, according to *Science*. Although born in Montreal, Dr. d'Herelle acquired his education in France. Before coming to the United States he was director of the bacteriologic laboratory of the quarantine service of Alexandria, Egypt, under the British government.

State Medical Meeting and Election—Dr. Ralph A. McDonnell, New Haven, was elected president of the Connecticut State Medical Society at its one hundred and forty first annual session, May 25, and Dr. Charles W. Comfort, Jr., New Haven, reelected secretary. The next annual meeting of the society will be held at Bridgeport May 23-24, 1934. Guest speakers included Drs. Hill Cook, Span, New York, on "Hypersensitiveness to Common Foods", Frederick W. O'Brien, Boston, "Dust Inhalation Diseases as Seen by X-Ray," and Julius Jarcho, New York, "Value of the Roentgen Ray in Gynecology." Local physicians included on the program were the following:

Winthrop M. Phelps, New Haven, Rational Use of Light as a Drug.
Douglas J. Roberts, Hartford, Practical Relationships of Irradiation to Medicine.
Robert M. Lewis, New Haven, Study of Theelin in the Treatment of Gonorrheal Vaginitis.
Philip G. McLellan, Hartford, Practical Consideration of Breast Tumors.
Daniel C. Patterson, Bridgeport, Fractures of the Spine.

DISTRICT OF COLUMBIA

Dr. Merritt to Give Davidson Lecture—Dr. Edwin A. Merritt will deliver the second Davidson Foundation Lecture, October 11, on "Roentgen Therapy in Hyperparathyroidism." The Davidson Foundation was established by the Medical Society of the District of Columbia in 1929 to provide for the lecture which is given every second year. The lecturer receives an honorarium of \$300. The foundation is a memorial to Edward Young Davidson who when president in 1916 conceived and led to completion the movement which provided a building for the society (THE JOURNAL, Nov. 14, 1931, p. 1472).

IDAHO

Personal—Dr. Eugene L. Spohn, Coeur d'Alene, has received a two year contract as health physician of Kootenai County.

Society News—Research in medicine and surgery was discussed at the semiannual dinner meeting of the Southwestern Idaho District Medical Society, May 10, in Boise. Dr. Arthur C. Jones, president of the society, led the discussion.

Annual Registration Due July 1—All practitioners of medicine and surgery holding licenses to practice in Idaho are required by law to be registered annually on or before July 1 with the Department of Law Enforcement, and at that time to pay a fee of \$2. If a licensee has not paid the annual registration fee by October 1, his license can be canceled and will be restored thereafter only on payment of the delinquent fees and a \$10 penalty.

ILLINOIS

Typhoid Epidemics—Twelve cases of typhoid, with two deaths were recently reported in Clinton, and about forty-five cases at DeLand. The Clinton outbreak was traced to a church supper, April 4, where a woman, whose son was ill with typhoid, purchased a quart of ice cream and took it to the kitchen. All the persons who subsequently came down with typhoid ate of this. Two children whose mother took home to them what remained of the quart of ice cream were ill, while their father, who ate none, escaped. According to the state health department, a well in the school grounds may have been involved in spreading typhoid among the school children at DeLand.

Chicago

Dr. Gorter Gives Tuberculosis Lectures—Dr. E. Gorter, head of the department of pediatrics, University of Leyden, Holland, gave a series of clinical lectures on "Tuberculosis in Childhood" at the University of Illinois College of Medicine, May 16-18 and May 20. These lectures were given under the Theodore B. Sachs Memorial Fund established by the Chicago Tuberculosis Institute.

Safrine Placed on Probation—A. J. Safrine pleaded guilty to violation of the medical practice act before Judge Dunne, March 24, and was placed on probation for one year, with the warning that the limit of the law would be imposed.

on him if he violated the medical practice act in the future. The warrant charging Safrine was issued Sept. 21, 1932, but the case was repeatedly continued. In 1930 Safrine, according to a newspaper report was sentenced to three months in the county jail and to pay a \$300 fine for a similar offense. At that time he was listed in the Chicago telephone directory as an 'M.D.' He was formerly a male nurse at Michael Rees Hospital, but the records of the American Medical Association fail to show that he ever was graduated by any reputable medical school.

Medical Week at the Century of Progress—During Medical Week, which is sponsored by the Chicago Medical Society and A Century of Progress, the following physicians will deliver addresses at 8 p. m., at the Hall of Science on the Fair grounds:

- June 19 James A. Britton Treatment of Tuberculosis. Channcey C. Maher Cause of Heart Disease.
- June 20 Edwin W. Ryerson Orthopedic Treatment of Infantile Paralysis. Austin A. Hayden Conservation of Hearing.
- June 21 Walter W. Hamburger, Heart Disease. Julius H. Hess The Infant of Today. Gilbert Fitz Patrick Cancer a Public Health Problem.
- June 22 Walter H. Watterson, Modern Facts on Tuberculosis.
- June 23 Philip H. Kreuscher The Ache in Your Back. Isaac A. Alt Pediatrics.

RADIO TALKS

- June 19 William Allen Pusey Purpose of the Medical Exhibits. Herman L. Kretschmer Your Health and Your Doctor.
- June 20 Franklin H. Martin One Hundred Years of Progress in Hospital Care.
- June 21 Edward H. Cary Dallas Texas, Saving Your Eyes.
- June 22 Morris Fishbein Frontiers of Medicine.
- June 23 Francis Berger Trudeau Saranac Lake N. Y., Prevention and Care of Tuberculosis.

INDIANA

Dental Building in Medical Center—The cornerstone of the new dental school of Indiana University was laid, May 16. The first floor will be given over to general offices, lecture rooms, and laboratories for anatomy, chemistry and metallurgy, histology and dental anatomy, bacteriology and pathology, and pharmacology and physiology. Surgery rooms, x-ray department, clinics and general waiting rooms will be located on the second floor, while the main clinic will be on the third floor with junior and senior laboratories. The exterior of the building will be of Indiana limestone. The laying of the cornerstone marked the first meeting of the newly organized Indiana University Dental School Alumni Association of which Frank A. Hamilton, D.D.S., Indianapolis is the first president.

Graduate Course Approved by State Association—A graduate course in general medicine surgery and the various specialties will be conducted at Indiana University School of Medicine, Indianapolis, June 26-July 1 with the approval of the Indiana State Medical Association. A second optional week will be available in any of the branches of medicine and surgery and the specialties, including ward walks, clinics, clinical pathologic conferences, round table conferences, assigned readings, special laboratory technique and topographic anatomy. A special feature of the course will be a meeting of the county medical society secretaries to discuss child health and maternal welfare in cooperation with the state board of health under the new plan. Symposiums will be held on diseases of the gastrointestinal tract, the thyroid, arteriosclerosis and fractures. A registration fee of \$2.50 will entitle any physician in good standing to the entire course.

Personal—Dr. Oscar D. Ludwig has been appointed health officer of Marion County, to fill the unexpired term of the late Dr. Frederick W. Mayer, Indianapolis.—Dr. James E. Gudgel celebrated his completion of fifty years in the practice of medicine in Cynthiana at a reception, April 2, attended by 303 guests.—Dr. Edward T. Thompson has resigned as administrator of the Indiana University School of Medicine and Hospitals Indianapolis effective May 1, after six years' service. He has been succeeded by Mr. J. B. Howe Martin purchasing agent and bursar of the Indianapolis Medical Center in a consolidation of both positions it was reported.—William B. Hice Terre Haute was elected president of the Indiana Tuberculosis Association at its annual meeting April 27.—Dr. John H. Gilpin Fort Wayne has been appointed commandant of the Indiana State Soldiers Home, Lafayette, succeeding Col. Charles F. Zillmer effective May 1.

KANSAS

State Medical Election—Dr. James D. Colt Sr. Manhattan is now president of the Kansas Medical Society. Dr. William T. Bowen, Topeka was chosen president-elect at the recent annual session and Dr. John F. Hassig Kansas City reelected secretary. The next annual meeting will be held at Wichita, May 9-11, 1934.

LOUISIANA

Personal—Dr. Isidore Cohn has been made head of the department of surgery of the Graduate School of Medicine of Tulane University, succeeding the late Dr. Alfred C. King.—Dr. Sidney C. Barrow Shreveport, has been appointed editor of the *Tri-State Medical Journal* (Arkansas, Louisiana and Texas), to succeed Dr. Jacob M. Bodenheimer, Shreveport, resigned.

Society News—The Tri-Parish Medical Society (Madison, East Carroll and West Carroll) was addressed in Lake Providence, May 2, by Drs. James B. Vaughan Monroe, on diagnosis of heart disease. George M. Street Vicksburg, diagnosis and treatment of malignant conditions of the breast, and Bert R. Burgoyne, Lake Providence, hypertension. Morris A. Stewart, Ph.D., Houston, Texas addressed the Seventh District Medical Society recently on 'Fly Larvae Therapy in Treating Bone Wound Infections'.—A symposium on syphilis was presented before the Orleans Parish Medical Society, May 22 by Drs. John Signorelli, Henry W. E. Walther, Oscar W. Bethea and Frederick L. Fenno.

MASSACHUSETTS

Society Observes Anniversary—The Massachusetts Society for Mental Hygiene marked the twentieth anniversary of its founding May 10, with an observance of the twenty-fifth year of the mental hygiene movement. At this meeting Mr. Clifford W. Beers, author of "A Mind That Found Itself" and founder of the mental hygiene movement, was made an honorary member of the society. Speakers included Drs. Ira S. Wile New York, on "Fact and Fancy in Mental Hygiene," Charles Macfie Campbell, Boston, "Work of the Massachusetts Society for Mental Hygiene" and James V. May, commissioner, state department of mental diseases. Herbert C. Parsons, president of the society, was chairman.

MICHIGAN

Tuberculosis Campaign—The Wayne County Medical Society, the Detroit Tuberculosis Sanatorium and the city department of health cooperated during May in a campaign to prevent tuberculosis in Detroit. A series of clinical conferences at the sanatorium was held in connection with the campaign.

Resolution on Medical Practice—The council of the Wayne County Medical Society adopted a resolution May 5 making it mandatory for members or groups of members of the society who are embarking on any plan that deviates from the usually accepted methods of conducting medical practice to submit that plan to the ethics committee before launching it. This action is based solely on an effort at fairness to every practicing physician and on an earnest solicitude for the public welfare the society's bulletin states.

Microscopes Stolen—In the same mail the Association received letters from doctors in Niles and Jackson, Michigan, reporting that their microscopes had been stolen from their offices. The numbers of the stolen microscopes were 191862 and 149513, respectively. *THE JOURNAL* Dec. 10, 1932, page 2042, published a general news item to the effect that microscopes were being systematically stolen from physicians' offices in Detroit and surrounding towns. The thieves in these cases apparently gained entrance to the offices through the use of master keys.

State Board Appointments—Dr. J. Earl McIntyre Lansing, is now secretary of the Michigan State Board of Registration, succeeding Dr. Nelson McLaughlin, Detroit. Appointments to the board include Dr. Harold L. Morris Detroit replacing Dr. McLaughlin, Dr. Eugene S. Thornton Muskegon replacing Dr. Charles A. Teifer Muskegon, and Dr. John E. Handy, Caro succeeding Dr. William F. English Saginaw. Dr. Theron G. Yeomans, St. Joseph, was reappointed. Offices of the state board have been transferred from the Macabee Building, Detroit, to the Hollister Building Lansing.

Dinner to Dr. Novy—The completion by Dr. Frederick G. Novy of forty-seven years on the faculty of the University of Michigan Medical School Ann Arbor, was observed by the Genesee County Medical Society at a dinner, May 10. In 1886, Dr. Novy made his first connection with the institution as assistant in organic chemistry. From 1887 to 1891 he was instructor in hygienic and physiologic chemistry, assistant professor 1891-1893, and junior professor, 1893-1902. Dr. Novy is now professor of bacteriology, a position held since 1902 and director of the Hygienic Laboratory at the University of Michigan.

MISSISSIPPI

Personal—Dr Gettis T. Sheffield has been appointed chief medical officer of the Veterans' Administration in Jackson.

MISSOURI

State Medical Election—Dr Warren L. Allee, Eldon, was installed as president of the Missouri State Medical Association at its annual meeting, May 3, and Dr Caus T. Ryland, Lexington, was named president-elect. Vice presidents elected at this time were Drs James F. Owens, St. Joseph, Hugh James Wisc, Sparta, and Perry W. Jennings, Canton. Dr Edward J. Goodwin, St. Louis, was reelected secretary. Mr E. H. Bartelsmeyer was appointed assistant secretary, a newly created position. He was formerly executive secretary of the St. Louis Medical Society. The next annual session will be held at St. Joseph, the time to be decided later.

State Board of Health Abolished—The State Department of Health of Missouri has been created to supplant the old state board of health, through the enactment of recent legislation. The position of secretary of the board has been abolished and provisions have been made for the appointment of a commissioner of health, to whom have been transferred all rights, powers and duties heretofore conferred on the secretary. Under the new law, the governor has appointed Dr Elmer T. McGaugh, Jefferson City, to serve as state health commissioner for a term of four years, succeeding Dr James Stewart, who also acted as secretary. Personnel of the new department includes the following physicians:

Emmett P. North, president, St. Louis, term expires May 1, 1937.
 Peter T. Bohan, vice president, Kansas City, term expires May 1, 1937.
 William T. Elam, St. Joseph, term expires May 1, 1937.
 William A. Clark, Jefferson City, term expires July 1, 1933.
 Herman S. Gove, Linn, term expires July 1, 1933.
 Edward S. Smith, Kirksville, term expires July 1, 1933.

Retiring members are Drs Stewart, Francis M. McCallum, Kansas City, and Horace W. Carle, St. Joseph.

NEBRASKA

Society News—Drs Frank M. Conlin and J. Frederick Langdon, Omaha, addressed the Omaha-Douglas County Medical Society, Omaha, May 9, on "Carcinoma of the Small Intestine" and "Treatment of Recurrent Hernia," respectively.

Personal—Dr John Buis, Pender, was guest of honor at a banquet given by the chamber of commerce, March 20, marking his twenty-fifth anniversary in the practice of medicine. —Dr Alfred Schalek has recently been elected president of the Omaha Dermatological Society.

State Medical Election—Dr Adolph Sachs, Omaha, was installed as president of the Nebraska State Medical Association at its annual meeting, May 25, and Dr Joseph Bixby, Geneva, was named president-elect. Dr Roy B. Adams, Lincoln, is the secretary. Lincoln was selected as the place for the next annual session in May, 1934.

NEW HAMPSHIRE

State Medical Election—Dr Robert J. Graves, Concord, was chosen president of the New Hampshire Medical Society at its annual session, May 17, and Dennis E. Sullivan, Concord, was reelected secretary. Manchester was selected as the place for the next annual meeting in May, 1934.

NEW JERSEY

Society News—A symposium on "Relationship Between the Medical Staff and the Board of Trustees of a Hospital" was presented before the Essex County Medical Society, Newark, May 11. Dr William D. Cutter, secretary, Council on Medical Education and Hospitals, American Medical Association, presented the view of organized medicine. Howard S. Cullman, president, Beekman Street Hospital, New York, that of the trustee, and Dr Frederic J. Quigley, Hoboken, president-elect, New Jersey State Medical Society, that of the staff. —Drs Joseph E. Roberts, Jr., and Charles R. Hutcheson addressed the Camden County Medical Society, Camden, May 2, on "X-Rays in Gastro-Intestinal Conditions" and "Roentgen Interpretation. Special Reference to the Osseous System," respectively. —Drs William H. MacKinney, Philadelphia, and Clyde Wilson Collings, New York, addressed the Atlantic County Medical Society, Atlantic City, April 14, on "Suprapubic Prostatectomy, Including Preoperative and Postoperative Treatment" and "The Plight of the Prostatic," respectively. —The Cumberland County Medical Society held its April meeting at the Vineland Training School with Dr P. Brooke Bland, Philadelphia, and Edgar A. Doll, Ph.D. Vineland, as speakers, on "Injuries of the Infant During Delivery and Motor Development of Birth Injured Children," respectively.

NEW YORK

Conference of Health Officers—For economic and other reasons, the annual Conference of Health Officers and Public Health Nurses will be omitted this year. A smaller conference, including county commissioners of health, district state health officers and health officers of communities of 10,000 and over, will be held in Albany, June 27-28.

Department for Treatment of Spastic Paralysis—A department has been created at the Reconstruction Home, Ithaca, for the treatment of spastic paralysis. The majority of patients under treatment are those associated with a congenital injury to the brain. The state department of health and the Cornell University Medical School are cooperating in the work.

University Awards Medal—The Chancellor's Medal of the University of Buffalo was recently awarded to Dr Francis Park Lewis, who has practiced in Buffalo since 1876. He is the founder of the International Association for the Prevention of Blindness and of the International Organization for the Control of Trachoma. In 1928 he received the Leslie Dana Gold Medal, awarded by the National Society for the Prevention of Blindness. The Chancellor's Medal was established under the will of Charles P. Norton, to be awarded annually for distinguished service to the city of Buffalo. It was presented to Frank A. Hartman, Ph.D., professor of physiology at the university, in 1932, in recognition of his work on Addison's disease.

New York City

Appointments at Polyclinic Medical School—Dr Russell L. Cecil has been appointed professor in the department of internal medicine at New York Polyclinic Medical School and Hospital, and Dr Joseph E. J. King, clinical professor in the department of neurosurgery. Dr Foster Kennedy has been appointed consulting neurologist.

Society News—The Medical Society of the County of Queens was addressed May 23, by Drs Frederick W. Rice and Henricus J. Stander on "Injuries to the Birth Canal and Their Prevention" and "Toxemias of Pregnancy," respectively. —At the May 3 meeting of the Harlem Medical Association Dr Joseph S. Diamond was elected president and Dr Louis Neuwelt secretary.

Dr Landsteiner Receives Medal—Dr Karl Landsteiner, since 1922 member of the Rockefeller Institute for Medical Research, was awarded the gold medal of the Dutch Red Cross Society, under the presidency of Prince Hendrik, April 19. The medal was awarded for Dr Landsteiner's discovery of the blood groups in relation to blood transfusion. Dr Landsteiner was awarded the Nobel Prize in 1930 for his work on human blood groups.

Lectures by Foreign Physicians—Dr Arthur Frederick Hurst, senior physician, Guy's Hospital, London, gave a lecture at the New York Academy of Medicine May 17, on "Some Disorders of the Esophagus." Dr Hurst discussed "Achlorhydria, Anemia and Degeneration of the Spinal Cord," May 15 at Mount Sinai Hospital. Dr Otto Loewi, professor of pharmacology, Medical Faculty, Karl-Franzens Universität Graz, Austria, lectured, May 19, at the hospital on "General Principles of Regulation and Adaptation in the Organism."

NORTH DAKOTA

Health Officers Elect—At the annual meeting of the official organization for North Dakota health officers at Fargo, recently, Dr Burton K. Kilbourne, Fargo, was made president, Dr Ernst G. Sasse, Lidgerwood, vice president, and Dr Arthur A. Whittemore, Bismarck, secretary.

Personal—Dr and Mrs Frederick B. Strauss celebrated their silver wedding anniversary at their home in Bismarck, recently. —At the annual meeting of the Richland County Medical Society at Wahpeton, Dr Tobias L. Burnberg, St. Paul, spoke on "Skin Conditions of Babies."

PENNSYLVANIA

Personal—Dr Walter R. Krauss, Wernersville, has been elected superintendent of the Pennhurst State School for Epileptics and Feeble-minded Children, Pennhurst, near Spring City. He succeeds Dr Albert H. Super, who resigned on account of ill health. The appointment was effective June 1.

Health Association Elects Officers—Dr Charles B. Crittenden, director, Kirby Memorial Health Center, Wilkes-Barre, was elected president of the Pennsylvania Public Health Association, May 17. Other officers include Drs James R. Smith, Erie, and John H. Doane, Mansfield, vice presidents.

and A. J. Bohl, Harrisburg secretary Philadelphia was selected for the place of the 1934 meeting

Philadelphia

Activities Concerning Economic Questions—Pursuant to recommendations made by its committee on medical economics (THE JOURNAL February 4, page 347), the Philadelphia County Medical Society has been active in bringing about changes in certain phases of medical practice in Philadelphia according to a recent report. Admission to free dispensaries has been regulated and cooperation with the board of health has been effected. Contract practice in Philadelphia hospitals has been stopped. The Philadelphia Health Council and Tuberculosis Committee has stopped its industrial practice. An agreement has been reached with insurance carriers relative to workmen's compensation laws, the working of which were especially condemned in the early report.

Pediatricians Honored—The Philadelphia Pediatric Society at a special meeting, May 18 presented medals of honor to Drs. Samuel McClintock Hamill founder of the society, and Howard Childs Carpenter professor of pediatrics in the University of Pennsylvania Graduate School of Medicine. Dr. Hamill made an address on "Recent Trends in Child Health" and Dr. Carpenter on "The Preservation of Child Health." Honorary memberships in the society were conferred on both physicians and also on Drs. Philip Van Ingen New York, and Kenneth D. Blackfan, Boston. Dr. B. Franklin Royer presented the medal to Dr. Hamill and Dr. Ralph M. Tyson that to Dr. Carpenter. Dr. Hamill for many years a member of the teaching staff of the University of Pennsylvania School of Medicine, is chief of the pediatric department in Howard, Presbyterian and Philadelphia Polyclinic hospitals. He served as chairman of the medical section of the White House Conference on Child Health and Protection in 1930 and is at present president of the American Child Health Association and chairman of the state emergency child health committee. He is a former president of the American Pediatric Society, American Academy of Pediatrics and American Association for the Study and Prevention of Infant Mortality. Dr. Carpenter was professor of pediatric hygiene in the graduate school and associate professor of pediatrics in the school of medicine of the University of Pennsylvania before he was appointed to his present professorship. He has been director of the department for the prevention of disease at the Children's Hospital of Philadelphia since 1913, medical director of the hospital since 1930 and pediatrician in charge of the children's department of the Graduate Hospital since 1926. Dr. Carpenter was secretary and treasurer of the American Pediatric Society from 1916 to 1931 and president 1931-1932 and was president of the Children's Hospital Association of America 1928-1930. He is now president of the Children's Bureau of Philadelphia.

SOUTH DAKOTA

Board Moves to Pierre—The transfer of offices of the South Dakota State Board of Health from Waubay to Pierre was to have begun, May 15, according to a recent announcement. Space has been provided in an annex recently constructed at the capitol.

State Medical Election—Dr. Edward W. Jones, Mitchell was inducted into office as president of the South Dakota State Medical Association at the annual meeting, May 17, and Dr. William G. Magee Watertown was named president-elect. Dr. Albert S. Ryder, Flandreau was elected vice president, and Dr. John F. D. Cook, Langford, reelected secretary. The next annual session will be held at Mitchell, the date to be decided later.

TEXAS

State Medical Election—Dr. Alonzo A. Ross Lockhart, was installed as president of the State Medical Association of Texas at its annual meeting May 11, and Dr. Samuel E. Thonipson, Kerrville, named president-elect. New vice presidents include Drs. Robert H. McLeod, Palestine, Benjamin C. Smith Hillsboro and Neil D. Buie Marlin. Dr. Holman Taylor, Fort Worth was reelected secretary. The next annual session will be held at San Antonio, May 7-10, 1934.

Personal—Drs. John S. McCelvey Temple, and Samuel A. Woodward, Fort Worth have been appointed to the state board of health, it is reported.—Dr. John R. Mahone, Austin, was recently named health officer of Cameron County to succeed Dr. William E. Spivey, San Benito.—Dr. William G. Gill San Antonio recently received a medal for conspicuous military service during the World War.

WISCONSIN

Society News—At the annual meeting of the Ninth Council District Medical Society, Stevens Point, April 27, Dr. Edwin G. Bannick, Rochester, Minn., conducted a clinic on cardiorenal diseases. Following the annual dinner, Dr. Herbert P. Benn Stevens Point, discussed spontaneous pneumothorax and Dr. Bannick, the sedimentation rate of the blood and the treatment of acute burns.

Instruction in Maternal and Child Welfare—Institutes on maternal and child welfare were conducted in twelve communities of Marathon County, with local health agencies and the state board of health cooperating. An average of twenty women at each institute was recorded. Subjects discussed included maternal and infant mortality, pregnancy and prenatal care, bandaging for varicose veins, care of the teeth in pregnancy, wardrobe for the expectant mother, labor delivery and postnatal care, importance of physical examinations, preparation of artificial feeding, and the preschool child. Demonstrations of technique also formed a part of the program. Speakers were local physicians and dentists, the county home demonstration agent, the county nurse, and a staff physician of the state board of health.

GENERAL

Reregistration Under the Harrison Narcotic Act—Physicians registered under the Harrison Narcotic Act must reregister on or before July 1. Each such physician must register with the collector of internal revenue of each district in which he maintains an office or a place for the treatment of patients. Failure to register within the time allowed by law makes a physician liable to a fine or to imprisonment, or to both and compels him to pay a penalty of 25 per cent on his annual tax when he does register.

Warning Against Impostor—A physician of Harrisburg, Pa., writes that an impostor came to the office to have his eyes examined, saying he was "Lieut. Com. L. C. Condon," a naval medical officer, in Pennsylvania on government business. A refraction was made and a prescription for glasses was given to the man. This he took to an optical firm, where he paid in advance for his glasses with a check made out for \$25, which was \$9 more than the bill. He then disappeared not returning for the glasses. The check was returned marked "no funds." The impostor was 5 feet, 6 or 7 inches tall, weighed about 180 pounds and had dark brown hair, blue eyes and a rather red face.

Dr. Fairchild Given Public Welfare Medal—David G. Fairchild D.Sc., Washington D.C., has been awarded the Public Welfare Medal by the committee on the Marcellus Hartley Fund of the National Academy of Sciences. The medal, which is given for "eminence in the application of science to the public welfare," will be presented to Dr. Fairchild at the next annual meeting of the academy in recognition of "his accomplishments in the development and promotion of agricultural exploration and the introduction of new and valuable plants into the United States." From 1906 until 1928 Dr. Fairchild was in charge of the office of foreign plant introduction, bureau of plant industry, U. S. Department of Agriculture. Since 1928 he has been pursuing special studies for the department.

Gorter Prize Awarded—Miss Anne Heyman was awarded the first prize of \$300 for her paper on "The Bacteriology of Gorter" by the American Association for the Study of Gorter at its annual meeting in Memphis, May 15-17, according to Science. The prize is awarded annually for the best paper based on original research on any phase of gorter. Miss Heyman's investigation was carried out in the Hygienic Laboratory at the University of Michigan under the supervision of Malcolm H. Soule. Officers elected at the meeting include Dr. Allen Graham, Cleveland, as president-elect, and Dr. Thomas M. Joyce, Portland, Ore., vice president. Dr. Robert M. Howard, Oklahoma City, was installed as president, succeeding Dr. Henry S. Plummer, Rochester, Minn. The next annual convention will be held in Cleveland.

Medical Library Meeting—The annual meeting of the Medical Library Association will be held at Northwestern University Medical Library, June 19-21. Dr. Walter R. Steiner, Hartford, Conn., will give the presidential address on "The Book and the Man, or Beaumont and His Physiology of Digestion." Other speakers will include Drs. Isaac A. Abt and Archibald Church, Chicago, Major Edgar Erskine Hume, librarian of the Army Medical Library, Washington D.C., Plan of the Fourth Series of the Index Catalogue of the Army Medical Library, Dr. Otto F. Kampmeier, "Union Catalogue of Medical Libraries of Chicago as Sponsored by the Institute of Medicine of Chicago", Dr. Eben J. Carey,

"Medical Exhibits at A Century of Progress" Dr Morris Fishbein, Editor, *THE JOURNAL*, Chicago, will give an illustrated address at the annual banquet, June 19, on "Medical and Dental Bookplates." Round table conferences will also form a part of the program.

Anniversary of Movement for Prevention of Blindness—The National Society for the Prevention of Blindness observed the twenty-fifth anniversary of the organized movement to save eyesight, May 24, with "open house" at its offices. The national society is the outgrowth of the New York State Committee for the Prevention of Blindness, which was organized by Miss Louisa Lee Schuyler in June, 1908, the Russell Sage Foundation giving a subsidy of \$5,000. In the beginning, this committee campaigned solely against ophthalmia neonatorum. Five years after the organized movement had been established, sight saving classes were inaugurated in Boston and Cleveland. The consolidation of the New York committee with the American Society for the Conservation of Vision resulted in the formation in 1915, of the National Committee for the Prevention of Blindness, which, in 1927, changed its name to the National Society for the Prevention of Blindness. Objectives of the organization are to ascertain causes of blindness or impaired vision, to advocate measures leading to the elimination of such causes, to bring the knowledge of eye hygiene in popular form to children and adults, and to act as a clearing house and stimulating agent for others engaged directly or indirectly in the prevention of blindness. The society's report for 1932 shows that the proportion of children who are blind from ophthalmia neonatorum, among new admissions to schools for the blind fell to 7 per cent, a decrease of 0.5 per cent since the preceding year. In the interests of economy, the society conducted only seventy-eight demonstrations in twenty-one cities, as compared with 103 demonstrations in forty-two cities during 1931. Through the society's publicity on the need for early treatment for the cross-eyed child, clinics were established for cross-eyed children in New York, Philadelphia and Cincinnati. A sight conservation program was inaugurated in Hawaii and the first sight-saving class on the island will soon open in Waikiki. The establishment of fifteen new sight-saving classes in 1932 brings the total in the United States to 413 in 121 cities. In addition to the publicity carried on in various publications, representatives visited seventy-one cities in twenty-seven states and Hawaii, as well as Austria, Switzerland, Czechoslovakia, France, Germany and England. Exhibits were lent to eighty-six communities during the year. The total disbursements for the general budget amounted to \$125,993.61, while the total income from general funds was \$106,386.53. The deficit of \$19,607.08 was met by drawing on the reserves, accumulated principally from legacies and memorial and special gifts. Lewis H. Carris is the managing director.

FOREIGN

Pediatric Congress—The third International Pediatric Congress will be held in London, July 20-22. Subjects of discussion will be "The Nature of Allergy and Its Role in Diseases of Children" and "The Prophylaxis of Milk-Borne Diseases." Dr Leonard Findlay, 61 Harley Street, London, W. 1, is secretary of the congress.

Personal—Dr Robert H. H. Goheen, an American physician in India, has recently been awarded the Kaiser-i-Hind gold medal by the king of England for meritorious services to the Indian people, the University of Chicago *Magazine* reports. Born in Kolhapur, Western India, Dr Goheen graduated from Rush Medical College in 1905, he is stationed at Vengurla, where he is in charge of St. Luke's Hospital, Hill-side Sanatorium, a leprosarium and the dispensaries, and is treasurer of the Western India Mission, the report stated.

Hastings Prize—Competition for the Sir Charles Hastings Clinical Prize, consisting of a certificate and a money award of fifty guineas, will close, December 31. This prize was established by the council of the British Medical Association for the promotion of systematic observation, research and record in general practice. The work submitted must include personal observations and experiences collected by the candidate in general practice. Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W. C. 1, not later than December 31, and the prize will be awarded at the annual meeting in July, 1934. Inquiries should be addressed to the medical secretary of the association.

Eastman Dental Clinic Dedicated in Rome—Ceremonies dedicating the George Eastman Dental Clinic in Rome, a gift to the Italian government from the late Mr. Eastman of Rochester, N. Y. were held, April 21. Harvey J. Burkhart, D.D.S., director of the Rochester Dental Dispensary, founded by

Mr. Eastman, formally presented the building to the government and Dr. Amedeo Perna, director of the new institution, accepted it. A bust of Mr. Eastman, presented to the clinic by Italian citizens of Rochester, was unveiled by Mrs. Burkhart following an address by Dr. Joseph Carlucci, Rochester. Hon. John W. Garrett, ambassador from the United States to Italy, read a cable of congratulation from President Roosevelt. Premier Mussolini inspected the building during the day. The Rome clinic is the second of five dental clinics in European cities for which Mr. Eastman set aside gifts of \$1,000,000 each. The first was opened in London two years ago. The cornerstone for the third, in Stockholm, was laid, April 29, at ceremonies in which the crown prince and princess of Sweden and Dr. and Mrs. Burkhart participated. It is expected that this clinic will be finished by September, 1934, and that the cornerstones for similar buildings in Paris and Brussels will be laid this autumn.

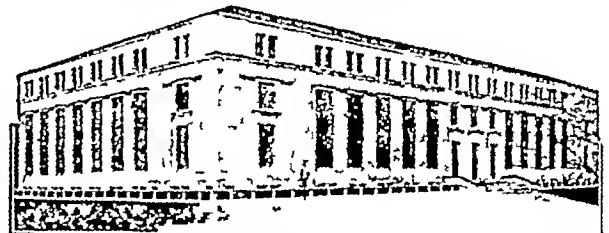

CORRECTION

The Color of the Nasal Septum—The reference in *THE JOURNAL*, April 29, at the bottom of page 1324 in the article on "The Color of the Nasal Septum" should have read: Fineberg, M. Laryngoscope, September, 1932. Furthermore, Dr. Fineberg used the carbon dioxide combining power in determining the acid base balance in a similar group of individuals instead of using the pH of the blood, as was stated by Bernheimer and Cohn.

Government Services

New Home of Public Health Service

Without formal dedication, the U. S. Public Health Service recently began moving into its new permanent building, at Twentieth Street and Constitution Avenue, Washington, D. C. The first official use of the building was in connection with the annual meeting of the National Advisory Health Council, May 16. Exclusive of the cost of the site, \$908,000 was expended for the construction of the marble building, which is

three stories high, with a wing at each end. There is also a wing in the middle of the building, with a combination auditorium and conference room on the first floor. An auditorium will be available on the first floor for conferences, lectures and displays of health exhibits, and a complete public health library will be installed on the second floor.

Celebration Postponed

The proposed celebration of the fortieth anniversary of the establishment of the Army Medical School, announced in the *Military Surgeon*, has been postponed. It is anticipated that the commemoration will take place during the fall.

Navy Officers Transferred to Reformation Camps

The transfer of 169 officers of the navy medical corps, junior grade, to the civilian conservation corps of the reformation camps was authorized, May 15, by President Roosevelt. These navy officers were on temporary assignment to the Veterans' Administration and were about to be dismissed because of economy measures with reference to medical and hospital treatment of nonmilitary service disabilities for ex-service men. The transfer was authorized rather than permit the officers to lose their positions in the government service. They will maintain their present naval status in regard to salary and will be eligible to restoration to their former assignments in the navy service. They will report for duty to the secretary of war and will be assigned to reformation camps where permanent medical officers will be needed. While the appointment of such a large number of medical officers will preclude the appointment of many physicians from civilian life to the camps, officials of the war department believe there will still be a great deal of work for civilian physicians on a part time basis.

May 20 1933

The Medical Curriculum

An important discussion has been aroused in Edinburgh by the publication of an article entitled 'Away with the Lumber of the Medical Curriculum,' by Dr Chalmers Watson senior physician to the Royal Infirmary. He regards the medical curriculum as overloaded in some respects and deficient in other respects, particularly in clinical training and in such subjects as dietetics, antenatal hygiene, physiotherapeutics and eugenics. He brings forward a number of proposals for reform.

- 1 No course of systematic lectures should exceed fifty, each subject being represented by a textbook adapted to the student's needs, some tutorial work and demonstrations should be added. These should be so planned as to cultivate the individual student's thinking powers.
- 2 In determining the number of systematic lectures for special subjects, the sole consideration should be the needs of the student. In regard to public health, for instance, it should be remembered that a public health appointment necessitates a special qualification, obtained after graduation.
- 3 The time for practical medicine must be at least trebled, while the time devoted to practical surgery and operations should be diminished, except in relation to outpatient work.
- 4 Facilities for clinical observation and instruction should be available at an earlier part of the curriculum than at present. These should begin not later than the second year.
- 5 Outpatient work in "dispensary" practice should be reestablished and organized as an integral part of the student's work.
- 6 Reorganization of all the basal scientific subjects is called for. Less detail and more applied instruction should be given.
- 7 In the third year the present "combined" class of medicine, surgery and pathology should be replaced by the former complete entity "The Principles and Practice of Medicine." This year's study is now a travesty of the word education, there is no surgery in the practice of medicine and, for all practical purposes, no morbid anatomy or pathology in a large part of the work of the practitioner.
- 8 The present class of "anatomy and physiology in relation to clinical medicine" should be abolished, as being largely a waste of time of both student and teacher. The lectures in "clinical medicine" should be reorganized and so as to secure cooperation of the teachers in special subjects, e.g., public health.
- 9 The time of senior medical students should not be unduly taken up by special classes for the final examination on subjects of very restricted practical importance for the student's future needs.
- 10 The time saved by sacrifice of unnecessary details should be devoted to subjects of the highest importance, e.g., dietetics, antenatal hygiene, eugenics. Finally, Dr Watson sums up the defects of the present curriculum as the prevalence of the cramming system, excessive teaching of specialized detail, and inadequate teaching in the principles and practice of preventive medicine.

In the *Scotsman* Dr William Robertson formerly health officer for Edinburgh, says that, while he agrees with a great deal in the scheme, it embraces too many reforms. The present-day student is better educated than his predecessors of thirty or forty years ago, but he is not a better healer. The all-round general practitioner, who used to be so highly esteemed, has almost disappeared. Wherever there is mass production, a certain amount of scamping must take place. There are too many students and too big classes. In the discussion, Edinburgh physicians generally agreed that the curriculum is overloaded. Botany and zoology ought to be linked together and taught as one subject, viz., biology in relation to medicine. Physiology ought not to be taught so much as a pure science

but more in relation to man. The student wastes much time in getting up abstruse operations he will never be called on to do. Most of the criticisms are in agreement with Dr Watson and only emphasize his points.

Whooping Cough in Old Age

At the Royal Society of Medicine, Prof A J Hall reported the case of a physician who had whooping cough when over 70, after forty years' work which included treating many cases of the disease. So violent was his coughing that he ruptured an abdominal muscle. The condition became distressing, after the abdomen had been strapped fits of coughing were followed by fibrillary twitching of the abdominal muscles, which went into a condition of spasm. He slept but little and always in a chair. Professor Hall pointed out the importance of recognizing these adult cases because there was a widespread view that old age was exempt, with the result that the infection might unwittingly be spread. In respect of whooping cough, as of bronchopneumonia, old persons reverted to childhood. He referred to records of other cases. Elliotson described the case of an archbishop aged 75, who had whooping cough shortly before he died. Sir William Jenner had it when he was over 65. Hale-White reported a case in a woman of 81 who had no signs of bronchitis. It seemed that as the child grew older a natural immunity was developed, but this did not suffice for protection later in life. Some of the patients who suffered in old age were known to have had the disease in childhood. Their immunity had disappeared. Others had never acquired immunity.

The Increase of Blood Transfusion

The report of the British Red Cross Society for 1932, which has just been published, states that the calls on the blood transfusion service continue to increase with arithmetical regularity, 2,442 calls having been received for 1932, against 2,078 for 1931, 1,627 for 1930 and 1,360 for 1929. The daily average was slightly under seven, but on eighty-four occasions ten or more were received. The personnel of the London service now numbers 1,304, 308 donors served for the first time, 308 for the second, 19 for the twentieth, 2 for the fortieth and 1 for the forty-fifth time. The number of hospitals using the service increased by twenty-four, the largest accession since 1926, and the last great hospital of London, which hitherto maintained its own service, has now abolished this and taken advantage of the facilities of the society.

May 3 1933

Protest Against Publicity of the Wine Industry

Wine merchants in France are resorting to publicity measures that go to shameful extremes. At a recent meeting of the Academy of Medicine, one of its members presented a vignette intended to be given as a reward to children in the schools of Alsace and supplied by the Office national du vin. On one side of the card is the portrait of Pasteur, below which is an autographed line (with his signature) which reads "Wine is the most healthful of beverages." On the other side are enumerated the amounts of various foods the caloric value of which is equal to that of a liter of wine. Dr Roux, who was a pupil of Pasteur, protested against the abuse in advertising of a statement of his teacher, although it is true that he wrote these words in an article, the context of which had been suppressed. Roux said it was a disgrace to see the name of the great scientist used to propagate among children such statements. It was distressing to learn that the distribution of these cards had been recommended to the teachers by a circular wrested evidently from the minister of public instruction by the deputies of the departments in which wine growing is the chief industry. Messieurs Barrier, Vaillard, Hayem and

Marcel Labbe expressed indignation over the audacity of the wine merchants and the weakness of the minister. The academy passed these three short resolutions: 1. No instruction pertaining to diet shall be given in schools without first being submitted to the Academy of Medicine. 2. The Academy of Medicine shall use its authority to prevent in the schools any form of publicity in favor of wine. 3. The Academy of Medicine stresses the danger that lies in the use in the schools of the term "healthful beverage" as a designation for fermented beverages. These resolutions were transmitted to the minister of public instruction. It is significant that none of the political journals that publish regular reports of discussions in the Academy of Medicine published any part of the session just described, no doubt being influenced in their action by the Office national du vin. The proceedings became known to the physicians in general only through the medical journals, especially the *Siecle medical* which is known for its independent attitude in such matters.

Bactericidal Effect of the Urine of Tuberculous Persons

Professor Courmont of Lyons had shown previously that the blood serum of tuberculous persons often exerts a bactericidal action on tubercle bacilli in cultures. In a recent communication to the Academy of Medicine, he reported on research done in conjunction with Gardere and Pichat, to discover whether this bactericidal principle is found also in the urine of tuberculous persons. He found that in some persons the urine possesses such bactericidal power. This potency is independent of the acidity and the chemical composition of the urine. The bactericidal substance is derived probably from the serum and is eliminated by the urine. Courmont studied also the influence of gold salts (in tuberculous persons and likewise in healthy persons) on the bactericidal potency of the urine and the blood serum. He injected "Sanocrysin" into fifteen persons and examined afterward the bactericidal properties of their blood serum and of their urine. He found that in tuberculous persons and in healthy persons gold salts increased or provoked the bactericidal potency of the blood serum and the urine toward tubercle bacilli. Even after almost complete elimination of the gold salts, the enhanced bactericidal potency persists for a time. The action is less when the patient begins to recover and it disappears for other reasons in cachectic tuberculous persons and in persons gravely affected. This property constitutes, therefore, an index of frank tuberculosis and the state of resistance. It has no doubt also a certain importance in the defense of the organism of the tuberculous person.

Undulant Fever

Undulant fever was discussed before the Academy of Medicine by Mr. Jullie, who described two well differentiated types of septicemia due to the Bruce micro-organism: (1) a benign type, lasting not more than three years, healing without sequelae, and very sensitive to various therapeutic agents, and (2) a polymorphous resistant type, tending to become chronic, causing permanent infirmities and a mortality of from 6 to 8 per cent. The latter type is the result of a secondary infection. The benign type is an infection due solely to *Alcaligenes*. It is therefore necessary in undulant fever, not to use only aerobic cultures in the Martin bouillon, slightly alkalized but to implant the blood cultures also on various aerobic and anaerobic liquid and solid mediums.

Examination of Drivers of Trucks

Heretofore a medical examination has been required only of drivers of public vehicles and of motor trucks. A medical examination of drivers of private cars is demanded only when the driver has caused an accident, and permission to drive a car is denied him if he is found to have any physical defect

that would imperil others. Medical examinations for drivers of motor trucks have been begun in all the large cities, the cost of such examination being paid by the applicant. But the ministerial decree neglected to establish a fee schedule, so that a medical examination costs \$1 in Paris and \$4 in Bordeaux. The result has been that many applicants come to Paris from Bordeaux for their examination. At present, twenty-five physicians are examining applicants at the prefecture of police in Paris, at the rate of from 120 to 125 applicants a day.

Overt Conduct of Students

Dr. Bellocq, recently appointed by the minister of public instruction as professor of surgical anatomy at the Faculté de médecine de Strasbourg, has been received by the students with shouts and groans and whistlings so disturbing that he has been compelled to retire. The dean, who intervened, was unable to appease the students, and the course has been omitted. The reason for the incident, which is supported by the physicians of Strasbourg themselves, is that the minister of public instruction has on two occasions appointed to chairs in the Faculté de médecine de Strasbourg physicians who had no previous connection with this faculty, one having come from Paris and the other from Toulouse. The minister is entirely within his rights and several professors of the Faculté de médecine de Paris came from Lille, Nancy and Montpellier. But they occupied professorships in those cities, whereas the two physicians designated for Strasbourg have been recently advanced to professorships and had been previously heads of clinics in other faculties of medicine. It was thought in Strasbourg that all chances for the students and for the heads of clinics of the local faculty to progress would be closed if the professors that the minister sent were always heads of clinics coming from other faculties of medicine. The minister of public instruction is disturbed and has been unable to reach a decision.

Cancer Mortality in Relation to Environment

In Munich, a city of 736,000 inhabitants, cancer was in 1932 far in the lead as a cause of death (1,381 deaths, as against 1,361 in 1931). Deaths from the other principal causes ran as follows: organic heart disease 880, heart failure or cardiac paralysis, 323, arteriosclerosis, 691, cerebral hemorrhage, 578, pulmonary tuberculosis 531 (1931 586). Per 10,000 inhabitants there were 18.8 cancer deaths. The Berlin statisticians G. Wolff and A. Jahn have established by an exhaustive inquiry that no influence of wealth or social position on the level of cancer mortality can be demonstrated. This fact that cancer is independent of environmental influences is evidence against its contagious nature.

Mortality from Influenza

According to reports of the federal bureau of health, the first quarter of 1933 lay in the shadow of the influenza epidemic, which increased the general mortality, while the marriage and the birth rates sank to new low levels. Per thousand inhabitants and on an annual basis, there were, in the first quarters of 1929-1933, 80, 81, 73, 71 and 67 marriages, 139, 139, 127, 116 and 111 living births, and 160, 113, 125, 111 and 132 deaths, respectively. In the large cities of Germany, the deaths from influenza of permanent residents, during the first quarter of 1933, amounted to 5,039, as compared with 6,788, 2,478 and 839 for the first quarters of 1929, 1931 and 1932, respectively. It has been the experience that the increase in the death rates from pneumonia, bronchitis, cardiac diseases, senile weakness and, to a certain extent, from tuberculosis may

be regarded as an effect of the influenza epidemic. In the main, the increase in mortality during the first quarter of 1933, except to the extent that it may be due to the fact that the average age of the population is constantly increasing, may doubtless be ascribed to unfavorable epidemiologic conditions of short duration and is not to be interpreted as evidence of a deterioration of the condition of the public health in general.

Tuberculosis Mortality

According to the observations of the statistician in the federal bureau of health, the tuberculosis mortality of Germany for the year 1931 was slightly lower than for 1930 nevertheless, the age groups 0-10 of both sexes and the age groups 15-20 in the male sex show an increase, which in young children up to age 5 exceeds the rate of 1928. These statements are the first statistically authenticated sign of an upward trend of tuberculosis mortality in Germany. This manifestation is doubtless due to an increased liability to infection resulting from overcrowding and from the quality of nutrition under the economic depression. From the publications of the federal bureau of health it may be seen further that now also the general mortality from pulmonary tuberculosis is increasing. During the first ten weeks of 1933, the deaths numbered 6,967 as compared with 6,583 in 1932.

Congress of Balneology, Definitions for Terms "Mineral Waters" and "Therapeutic Springs" Established

The Balneologische Gesellschaft has been holding its annual session in Baden-Baden. Among other things, precise definitions for the terms 'mineral waters' and 'therapeutic springs' were established, with a view to combating abuses.

Special interest attached to the communication of Prof. E. Hesse of Breslau to the effect that certain metals—for example, copper, iron and arsenic—in extremely small quantities, as well as small quantities of water from springs containing iron and/or arsenic, have the capacity of preventing intoxications in animals, due to thyroid extract. That would explain the favorable action of such springs on exophthalmic goiter.

Attention may be called to the discussions on technical health resort problems. Careful observation of therapeutic springs furnishes evidence that they are subject to influences from earthquakes, also climatic changes may influence them, but further observations are needed to show to what extent.

The main topic was 'The Importance of Diagnosis in Health Resort Practice'. Professor Beckmann of Stuttgart, among others, emphasized that the acid-base equilibrium of the body may be influenced not only by the food intake but also by a therapeutic bath regimen; furthermore that cold baths have a tendency to cause a shifting toward the acid side and warm baths a shifting in the alkaline direction. Beckmann regards the manifestations of the acid-base equilibrium as a good criterion for the determination of the effects and therapeutic value of springs. Other papers dealt with the effects of baths and of health resorts in general on various disease conditions: diseases of metabolism, tuberculosis, asthma and the like.

The second main topic dealt with 'Climatic Science'. For instance, a study of the air currents of a health resort is important in connection with the laying out of streets and the location of buildings. Götz-Arosa brought out that the publicity literature of health resorts concerning ozone laden air, unless based on exact measurements which is not usually the case, must be treated with skepticism. Linke of Frankfurt-on-Main called attention to the apparatus constructed by Frankenburg, which makes possible a quantitative evaluation of a given climate from the standpoint of ultraviolet radiation. According to Flach, the graphic representation of climate makes it possible to study the factors that cause disease or promote health and thus to establish the dosage of climatic treatment in health resorts.

ITALY

April 15, 1933

A Course in Endocrinology

A special course dealing with the subjects of endocrinology and arthrology, under the auspices of the Istituto interuniversitario italiano, is to be held in Varese. Professor Ponticaccia will have charge of this course. Lectures will be given on the anatomic and physiologic foundations of endocrinopathy and on the pathology and clinical manifestations of the glands of internal secretion. In addition, acute articular rheumatism, other infectious forms of rheumatism, and chronic arthropathies and their treatment will be discussed.

Treatment of Bronchopulmonary Suppurations

Professor Pieri has tried in a number of cases the intravenous injection of alcohol in the treatment of bronchopulmonary suppurative processes and reported his results to the Società medico-chirurgica of Belluno. The method was recently proposed by Landau, Fejgin and Bauer. It appears that the alcohol thus injected is taken up through the lungs by the reticulo-endothelial system and causes an attenuation of the virulence of the microorganisms and a more abundant local production of antibodies. The injections are given in the form of a 33 per cent solution of alcohol, in doses of from 10 to 20 cc, every day or on alternate days. In three grave cases the treatment appeared to have a clearly favorable effect, following a number of injections ranging from ten to seventy. The treatment was more effective, the more recent the suppurative process was. It is contraindicated in patients affected with hepatic or renal lesions.

Protection Against Noxious Gases

The superior council of health has been studying the subject of protection against harmful gases and dusts in the industries. The council has expressed itself in favor of including such protective apparatus in the medical and surgical equipment with which industrial establishments must, by law be provided. As a result, the production and sale of gas masks and of other apparatus for individual protection will be subjected to special rules and regulations.

Distribution of Deaths from Tuberculosis

Dr. Cramarossa of Turin made an accurate survey of the distribution of deaths from pulmonary tuberculosis occurring from 1920 to 1930 in that city, with a population of half a million. It appeared that only sixty-three of the streets, squares and roads located in the various quarters of the city were immune from infection, and that in a given street the mortality was greater, the more evidence there was of overcrowding, the worse the economic conditions of the people were, and the more laborious their everyday work was. The mortality from tuberculosis presented in the outskirts a course not essentially different from that noted in the central areas. In the outskirts, other factors predominate over overcrowding, namely, defective hygienic conditions and poor dwellings.

Circulatory Velocity of the Blood

Dr. Bonadico, using a 50 per cent solution of calcium chloride intravenously, determined the speed of the circulation of the blood in seventy persons and reported his results to the Accademia Linceiana di Roma. Taking account of the interval of time between the injection and the rise of temperature in various parts of the body, the speaker found that, in comparison with normal persons, the circulation is retarded in cases of cardiac decompensation, the retardation running parallel with the gravity of the decompensation. A similar retardation was noted in chronic nephritis. In bronchial asthma, pulmonary emphysema and fever, the circulatory speed does not undergo any notable changes from normal.

Address of Professor Mistal

Professor Mistal of Montana Switzerland, delivered an address before the Sicilian section of the Federazione per la lotta contro la tubercolosi on the division of pleural adhesions to aid collapse of the lung during artificial pneumothorax. In speaking of the indications for the division of adhesions, he emphasized the value of the radiologic examination the stereo-radiographic examination and thoracoscopy for the determination of the site of the adhesions. He mentioned four types of adhesions according to the classification of Maurer, and explained the progress of technic by means of which the dangers of complications can be reduced to a minimum. Concerning the results the speaker stated that, owing to the fact that, by division of the adhesions it is possible to reduce notably the failure of incomplete pneumothorax and to diminish by about one half the thoracoplastic operations the intervention should always be considered after a careful study of all the criteria that determine the indications in individual cases.

Professor Gabbi's Death

Prof Umberto Gabbi, senator, and director of the Clinica medica of the University of Parma died suddenly from heart disease while traveling by train to Rome. He graduated at an early age and entered the Clinica medica at Florence as an assistant at first of Professor Federici and later of Pietro Grocco. At the age of 35 he was appointed extraordinarius in medical pathology, and at the age of 45 he became head professor at the University of Messina. In the terrible earthquake of 1908, members of his family lost their lives and his clinic was destroyed. He then went to Rome and entered the Scuola di Guido Baccelli from January, 1918, he directed the Clinica di Parma. He was the author of about 200 scientific publications, most of them pertaining to tropical diseases. Monographs of Professor Gabbi on the spleen the kidneys and the nerves are found in Cantani and Maragliano's treatise on pathology and therapy. He published a treatise on general symptomatology and another on symptomatology of the nervous system, a treatise on tropical pathology, and a work on clinical lesions. Recently, although 70 years old he conducted a mission into the interior of the Italian colony of Eritrea.

Heated Discussions on the Medical Amendments

The amendments to the medical laws unexpectedly gave rise to serious dissension in both houses of the diet. Few, if any, occasions can be recalled when medical problems have been discussed so heatedly as in this session. The government had been led to believe that the amendments would pass the diet without any difficulty, but suddenly strong opposition appeared to two items in the amendments, which read as follows: Article 4 Matters necessary for inauguration, establishment arrangement and control shall be ordained by government order. Article 6 Practitioners shall keep record cards with detailed information about the patient, which shall be kept for five years. The local government may censor these cards at any time if need be.

Article 4 does not impose restrictions on the qualifications of a person who establishes a hospital or clinic. The government intends to permit any unlicensed man to have a hospital or clinic, employing licensed practitioners if it is kept for the benefit of the public and not for profit. The government desires the formation of a health union or the like for the lower classes, while it is a great menace to private practitioners. On these points, some members of the Japan Medical Association started a movement to oppose the government and the managers of the association. The Japan Medical Association had lost control over the members, and this fact troubled

the home office greatly. The house of peers appointed a special committee of nine to discuss the measure. After a few meetings the bill passed the upper house but with the following two reservations: 1 When a layman establishes hospitals or clinics, these shall not be for profit. 2 Censorship of records is apt to cause anxiety and apprehension to practitioners and patients, and it shall be enforced only when administrative procedures inevitably require it. The censor shall be limited to licensed physicians or pharmacists.

After the bill passed the upper house, it was presented to the lower house where a special committee of eighteen began its consideration and discussion. The home office has difficulty in having any kind of bills pass the diet and the medical amendments were no exception. The majority party was planning to do nothing about them, through considerations of political policy when, on the day last but two of the session, the committee concluded to amend article 4 to read as follows: Unlicensed practitioners cannot establish hospitals or clinics, except when approved by government order. Article 6 passed with the proviso that the censorship of record cards shall be undertaken only when it is necessary for administrative purposes. The two houses, therefore, having disagreed on article 4, had to meet in joint conference on the last day but one of the session. The situation was complicated but at last an agreement was reached by amending article 4 to read that others than licensed physicians, excluding any public corporation shall obtain the sanction of the local governor (in Tokyo, the superintendent governor of metropolitan police) before establishing a hospital or clinic. The government was obliged to agree to this amendment. Imperfect as the new legislation is it sanctions the long entertained desire to amend the old medical laws. But an important problem was left unsolved through the Japan Medical Association losing control of its members. The government will not rely on the association hereafter, because of this failure. Strangely enough, amendments to the dental law passed the diet without opposition. It is said that the Japan Dentist Association was able to hold its members in line.

Medical Meetings

As usual each year, the general meetings of almost all the medical societies were held the first week in April. The meetings were highly successful. In Fukuoka, where the Kyushu Imperial University is located, four general meetings were attended by more than 2,000 members. In Kyoto, the following meetings were held:

The Society of Internal Medicine met under the chairmanship of Professor Matsuo. The papers were limited to the subject of liver disease. Dr. Inoue gave a physiologic review on liver disease before an audience of 1,300. More than sixty papers were read.

The thirty-fourth general meeting of the Japan Surgical Society was opened by Dr. Goto, president, and sixty papers were read. Special talks were given by Dr. Kuchi on injury to the peripheral nervous system and by Professor Shioda on the diagnosis and treatment of intestinal obstruction.

The Tuberculosis Society met for three days. Professor Miyagawa, in his paper on the salt-free diet, concluded that its effect was uncertain, while Dr. Haruki reported that this treatment was quite effective. Some ninety papers were read.

The Japan Roentgenologic Society split into two parts during the present session over the election of its president. The old society was founded and developed as a branch of orthopedic surgery, while the newly organized society, for the first time had its president from among the roentgenologists. Professor Fujinuma of Keio University became the first president of the new Japan Roentgenotherapeutic Society. The chief topic at the meeting was tuberculosis of the spine, and more than sixty papers were read.

The Endocrinologic Society was addressed by Dr Mizutani on the influence of insulin, suprarenal capsule or iodine on exophthalmic goiter. Professor Matsuoka reported that the chief element in the suprarenal cortex is sulphur and that sulphur is effective in promoting the sexual function of the male.

In the Kyushu Imperial University Medical Department the following societies held meetings.

The twenty-third general meeting of the Japan Pathologic Society scheduled too many papers to be read in three and one half days and half of them were left unread. A controversial topic was the cause of tsutsugamushi disease, especially the cultivation of Rickettsia.

The Japan Hygienic Society heard a special paper on the birth rate in Japan by Professor Furuya, over eighty papers were read.

The Japan Microbiologic Society heard talks on children's dysentery. The late Dr Asakawa's scholarship was awarded to Drs Kodama, Takahashi and Kawano in recognition of their research on Manchurian fever and typhus.

Smallpox

Since the first outbreak of smallpox this year in the southwestern province of Kagoshima, which is near Korea, the number of cases has amounted to 180, according to official reports. In Tokyo there are twelve cases among Koreans, who came over to Tokyo just before they were found to be suffering from smallpox. The authorities are quite busy in preventing its further spread. The police bureau ordered that the regular vaccination this year should be done much earlier throughout the country.

Infants' Week

The Central Social Welfare Association is going to hold an "infants' week" in May, one day of which will be "mothers' day." A pamphlet concerning the feeding of children, and instruction for mothers, will be given to pregnant women. An infants' evening over the radio and lectures will be held in various places. A prize is offered for a design for posters to be used during the week. Medical examinations will be given to children and babies. A prize contest is to be held for the healthiest baby, and during the week consultations on children's health will be held free of charge. In this movement, many social welfare bodies will join, such as the Red Cross society, the ladies' patriotic league, the medical associations, the home office and education office, and the midwives' association.

May 1, 1933

Olfactory Disorders in Relation to Cranial Trauma

At a session of the Société d'études medico chirurgicales Drs Helmsmoortel, Nyssen and Thienpont presented a paper based on a large number of cranial traumas, which threw light on the disorders of olfaction.

Anosmia of traumatic origin has long been considered rare. It appears, however, that such disorders are rather frequent and are important in evaluating the intensity of the traumatism suffered. The authors collected forty-three cases of cranio-cerebral traumatism and studied the sense of smell in these patients. The examinations were made at varying periods of time after the traumatism. They used the series of odoriferous substances utilized by Mr Nyssen in his researches. The first group of substances consisted of odors having no or very weak olfactory action, the second group of substances represented odors with a marked olfactory action, together with excitation of the trigemini and the taste. In forty-three cases of traumatism the authors observed six cases of complete and enduring anosmia, two cases of complete anosmia changing to

hyposmia, seven cases of partial or variable anosmia or hyposmia, one case of simulated anosmia, and two cases of anosmia explainable by endonasal lesions existing before the accident. In twenty-three examinees there were no olfactory disorders at the time of the examination.

The disorders follow nearly always a grave traumatism. Of the nine traumatized persons presenting slight olfactory disorders, only one had suffered a fracture of the ethmoid bone. In six cases of complete anosmia, five persons had suffered a fracture (three of the ethmoid bone and two of the cranial wall). In the twenty-six olfactory cases there appears to have been no fracture of the ethmoid bone, there were, however, eleven cases of cranial fracture: four of the petrous bone, three of the cranial wall, one of the base of the cranium, one of the apex, one of the occiput and one of the frontal bone. It appears, therefore, that when anosmia is complete and permanent, fracture of the ethmoid bone is frequent.

The Blood Sugar in Melancholia

At the eleventh Belgian Congress of Neurology, Massaut discussed among other things the changes in the vegetative nervous system in states of melancholia and anxiety. He concluded that the metabolism of nitrogen does not present, in cases of depression and anxiety, any characteristic disorders. Sometimes there is acidosis, and sometimes there is alkalosis. In a great number of patients with melancholia the basal metabolism is retarded, whereas it is more likely to be increased in anxiety. Hypercholesterolemia is the rule in melancholia and is possibly the cause of endocrine disorders, a vagotonic state or intoxication. Hyperglycemia and glycosuria have often been observed in patients with melancholia and especially in those with anxiety. In these patients there are slight modifications of the calcium and potassium indexes of the blood. The magnesium index is, however, normal. The endocrine changes are frequent, in some cases there is a parallelism between the mental and the glandular disorders. In these patients one observes a marked neurovegetative disequilibrium, sometimes vagal and sometimes sympathetotonic. The organic endocrine and neurovegetative disorders appear closely associated.

Results of Collapse Therapy

Addressing the Société belge de tuberculose, De Winter reported the results secured over a period of six years with surgical collapse therapy. He emphasized that the persons thus operated on are all gravely affected and do not usually have the means of taking prolonged courses of treatment. Of about 150 patients to whom surgical treatment was proposed but rejected, 120 have died, twenty are cachectic, one is an invalid, while about ten patients have been lost track of, most of them probably dead. Surgical collapse should be selective, radical and progressive and should be done by a combination of the various methods available. Apicolysis has stood well several tests. De Winter holds that pleural detachment is a much more dangerous intervention than some authors declare. Professor Sebrechts operates at present on his patients under high epidural anesthesia. It appears likely that if this method can be perfected it may constitute the ideal anesthesia for the surgery of pulmonary tuberculosis. Since the results of surgical treatment depend chiefly on the previous condition of the patient, De Winter divides his patients with reference to collapse therapy into four classes: good, mediocre, bad and bad bilaterally. In a series of 181 patients operated on, the author reported 64 per cent of failures and 36 per cent of successful outcomes. The successful outcomes were distributed as follows: 58 per cent for the good cases, 54 per cent for the mediocre cases, 26 per cent for the bad cases, and 22 per cent for the bad cases bilaterally. In 154 cases of apicolysis, the author reported twenty-one postoperative deaths during the week following the intervention.

Marriages

WILLIAM C. MEBANE, JR., Wilmington N. C., to Miss Pauline Mae Eckert at Bethlehem, Pa., April 13

WILMER HOWARD PAINE, JR., Charlottesville, Va., to Miss Mildred Goadby Black of Lynchburg, April 22

STIRLING SHARP MCNAIR, Elkins Park, Pa., to Miss Clarissa Walton of St. Davids, April 27

HENRY AMISS HORNTAL, Washington, D. C., to Miss Ellen Joanna Hall, May 13

DUDLEY MERRILL, New York, to Miss Katherine Park of Englewood, N. J., June 5

MILTON C. SCHELL, Chicago, to Miss Dorothy Wagner of Springfield, Ill., April 29

CARL OLIVER DIAMOND, West Allis, Wis., to Miss Ruth Sibil Heimovitz, April 25

FRANCIS CHARLES LANE to Miss Rosemary Stange, both of Merrill, Wis., May 3

SIGMUND NEWMAN, Vienna, Va., to Miss Rita Lessner of Richmond, May 14

Deaths

John Wesley Bell, Minneapolis, Medical College of Ohio, Cincinnati, 1876, an affiliate Fellow of the American Medical Association, member of the House of Delegates of the American Medical Association, 1919-1923, emeritus professor of medicine and at one time professor of physical diagnosis and clinical medicine, University of Minnesota Medical School, in 1886 professor of the theory and practice of medicine at the Minnesota Hospital College, past president of the Minnesota State Medical Association, Hennepin County Medical Society and the Minnesota Academy of Medicine, member of the state senate, 1891-1895, for ten years member of the Hennepin County Sanatorium Commission, visiting physician at Northwestern Hospital and consulting physician at Swedish, St. Mary's and Asbury hospitals, aged 80, died, May 16, of chronic pulmonary tuberculosis

Carbon Gillaspie ♂ Boulder, Colo., Colorado School of Medicine, Boulder, 1905, past president of the Boulder County Medical Society, associate professor of anatomy at his alma mater, member of the American Association of Anatomists, fellow of the American College of Surgeons, served during the World War, for six years member of the city council and board of education, on the staff of the Community Hospital, aged 53, died, May 5, of coronary thrombosis

Henry Dickson Bruns ♂ New Orleans, Jefferson Medical College of Philadelphia, 1881, emeritus professor of diseases of the eye New Orleans Polyclinic, member of the American Ophthalmological Society, in recognition of his nearly fifty years' service was honored recently when a bronze plaque was placed in the diagnostic room of the Eye, Ear, Nose and Throat Hospital, aged 73, died, May 19, of angina pectoris

John Perry Seward, New York, New York Homeopathic Medical College and Hospital, 1893, formerly professor of the practice of medicine, New York Medical College and Hospital for Women, on the staffs of the Laura Franklin Hospital, Metropolitan Hospital, New York Ophthalmic Hospital, Fifth Avenue Hospital and the Broad Street Hospital, aged 64, died, May 22, of arteriosclerosis and coronary disease

Herbert Dana Schenck, Brooklyn, New York Homeopathic Medical College, 1884, fellow of the American College of Surgeons on the staffs of the Carson C. Peck Memorial Hospital, Brooklyn Nursery and Infants' Hospital, Prospect Heights Hospital and Brooklyn Maternity and the Cumberland Hospital, aged 76, died, May 20

John King Winer, Chicago, Rush Medical College Chicago, 1884 assistant professor (extramural) medicine, Northwestern University Medical School, on the staff of the Passavant Memorial Hospital, aged 70, died suddenly, May 14, of arteriosclerosis, myocarditis and coronary thrombosis

Herbert Adolph Brown ♂ Cincinnati, Medical College of Ohio, Cincinnati, 1905, member of the Associated Anesthetists of the United States and Canada, served during the World War, on the staff of the Jewish Hospital, aged 50, died, May 22, of heart disease

Clarence S. Eldredge, Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1891 member of the Medical Society of the State of Pennsylvania, aged 64, died, May 25, in the Hahnemann Hospital, of cerebral hemorrhage

Floyd McJunkin Allen, Washington, D. C., University of Michigan Medical School, Ann Arbor, 1918, member of the Medical Society of the District of Columbia, served during the World War, aged 38, died, May 22, of pneumonia

Sol Rosenblatt, Chicago, Reliance Medical College, Chicago, 1909, Bennett Medical College, Chicago, 1912, member of the Illinois State Medical Society, served during the World War, aged 58, died suddenly, May 22, of heart disease

Gordon M. Hume, Sherbrooke, Que., Canada, McGill University Faculty of Medicine, Montreal, 1905, fellow of the American College of Surgeons, attending surgeon to the Sherbrooke Hospital, aged 49, died, April 10

David H. Young, Fulton, Mo., Missouri Medical College, St. Louis, 1878, member of the Missouri State Medical Association, on the staff of the State Hospital, Number 1, aged 75, died, March 22, of pernicious anemia

Julian Davis Arbuckle, Lewisburg, W. Va., University College of Medicine, Richmond 1901, county health officer, aged 58, died suddenly, May 3, in Maxwellton, of coronary occlusion and angina pectoris

Oscar Noel Moody, Tennessee City, Tenn., Vanderbilt University School of Medicine Nashville, 1882, University of Nashville Medical Department, 1883, aged 71, died suddenly, April 29, of heart disease

Louis A. Thompson ♂ Veterans Administration Home, Va., Bellevue Hospital Medical College, New York, 1897, governor and manager of the Veterans Administration Home, aged 60, died, April 14

George Milton Marshall, Wheelersburg, Ohio, Columbus Medical College, 1880, Bellevue Hospital Medical College, New York 1885 member of the Ohio State Medical Association, aged 82, died, April 11

Grace Peckham Murray, New York, Woman's Medical College of the New York Infirmary for Women and Children, 1882 member of the Medical Society of the State of New York, aged 84, died, April 8

William Andrew Dittenbaugh, Chicago, Hahnemann Medical College and Hospital, Chicago 1912, aged 56, died, May 27, in a hospital at Columbia City, Ind., of peritonitis, following a colostomy

Clyde Wallace Parsons ♂ Sweet Springs, Mo., National University of Arts and Sciences Medical Department, St. Louis, 1917, served during the World War, aged 42, died, May 7, of pneumonia

Frank Conger Smith ♂ Yankton, S. D., University of the City of New York Medical Department, 1894, fellow of the American College of Surgeons, aged 64, was killed, May 4, when gored by a bull

Frederick A. Kraft, Milwaukee, American Medical College St. Louis, 1894, Barnes Medical College, St. Louis, 1899, formerly city health commissioner, aged 62, died, May 13, of valvular heart disease

Frank Edwards Coudert, Guthrie, Okla., New York University Medical College, 1891, aged 62, died, April 30, at the Masonic Home, Wallingford, Conn., of arteriosclerosis and cerebral hemorrhage

Clarissa M. Clay Richardson, St. Paul, John A. Creighton Medical College, Omaha, 1917, aged 37, died, April 16, in St. Joseph's Hospital, of bronchopneumonia and toxemia of pregnancy

Emmett Eugene Pollard, Graysville, Tenn., University of Alabama School of Medicine, 1916, served during the World War, aged 39, died, April 20, in Laverne, Ala., of chronic nephritis

Carolyn Stephen Cronin, San Francisco, St. Louis University School of Medicine 1922, aged 37, died, April 1, in the Letterman General Hospital, of atrophic cirrhosis of the liver

Joseph Bowditch Gerould, North Attleboro, Mass., Harvard University Medical School, Boston, 1881, member of the Massachusetts Medical Society, aged 77, died, March 28

Peter Stocksclaeder, Rochester, N. Y., University of Buffalo School of Medicine, 1881, member of the Medical Society of the State of New York, aged 76, died, March 23

John Collier McRae, Atlanta, Ga., Emory University School of Medicine Atlanta 1918 served during the World War, aged 36, was found dead, May 6, of heart disease.

Loren Everett Wilson, Los Angeles, College of Physicians and Surgeons, Los Angeles 1912 served during the World War, aged 48, died, April 16, of diabetes mellitus

Ernest B Loudin, Olympia, Wash. Barnes Medical College, St. Louis, 1900, member of the Washington State Medical Association, aged 62, died May 24, of heart disease

Frank Horace Wray, Omaha, College of Physicians and Surgeons Keokuk, Iowa, 1887 aged 83 died May 2, in Long Beach, Calif., of carcinoma of the liver and gallbladder

Roger Irving Clapp, Inglewood Calif. Tufts College Medical School, Boston, 1914, aged 49, died, April 2, of hypertension, cerebral hemorrhage and bronchopneumonia

Fernando Hardinger Wade Columbia Mo University of Missouri School of Medicine, Columbia, 1893 aged 68, died, April 27, of cerebral hemorrhage and arteriosclerosis

James Magner McElroy Los Angeles, Bennett Medical College, Chicago, 1913 member of the Illinois State Medical Society, aged 49, died, May 1, of heart disease

Ernest Morrison Currie Detroit Michigan College of Medicine and Surgery, Detroit, 1902 aged 56 died, May 16, of chronic myocarditis and coronary thrombosis

Ervin A Mader Chicago, Loyola University School of Medicine, Chicago, 1922, aged 39, died, May 26 in the Edward Hines, Jr., Hospital, Hines, Ill., of tuberculosis

Oscar William Sherwood Westport Calif., College of Physicians and Surgeons of Chicago 1885 aged 70, died, May 14, in Fort Bragg of cardiorenal disease

Michael Joseph Banks, Jacksons Gap Ala., Atlanta Medical College, 1890, member of the Medical Association of the State of Alabama, aged 75, died April 4

Robert Henry Harper Afton Okla. Missouri Medical College, St. Louis, 1895 past president of the Ottawa County Medical Society, aged 64, died, February 22

James Archibald Keown, Los Angeles, Harvard University Medical School, Boston, 1894, aged 58, died, April 11, of injuries received in an automobile accident.

Leon S Dalsimer, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1900, aged 53, died, May 10, of hypertension and cardiovascular disease.

Charles Edwin Tegtmeyer, Philadelphia Hahnemann Medical College and Hospital of Philadelphia, 1892, aged 65 died May 12, of carcinoma of the lungs

William Thomas Slemmons, Santa Monica, Calif., Rush Medical College Chicago, 1884, aged 79, died, May 4, of chronic myocarditis and arteriosclerosis

Amy J A G Rees, Costello, Pa., College of Medicine and Surgery (Physio-Medical), Chicago, 1901, aged 76, died, May 1, in Corry, of pernicious anemia.

Henry Sidney Kergan Oakland Calif., Michigan College of Medicine and Surgery, Detroit, 1894, aged 62, died suddenly, May 10, of heart disease.

Herschel A Snorf, Greenville, Ohio, Miami Medical College, Cincinnati, 1886 aged 70, died, May 15, in the Greenville Hospital, of intestinal obstruction.

Duffield Dufferin MacGillivray, Pine Village Ind., University of Illinois College of Medicine, Chicago, 1906, aged 58, died, May 2, of paralysis agitans

William Clement Butler, Fort Ritner Ind (licensed, Indiana, 1897), aged 78, died May 19, in Bloomington, of acute myocarditis and arteriosclerosis

Constantine Leventis, Detroit, National University of Athens School of Medicine, Athens, Greece, 1891, aged 64, died May 6, of heart disease.

William Warren Conant Spencer, Brookline, Mass., Eclectic Medical College of Maine, Lewiston, 1884, aged 78, died April 4, in Miami Fla

Lewis Carthrae, Jr. Corder, Mo. Kansas City Medical College, 1904, served during the World War, aged 60, died, March 11, of heart disease.

Charles Mitchell, St. Louis, St. Louis College of Physicians and Surgeons, 1906, aged 64, died, May 2 in the City Hospital, of heart disease.

Mary J Lobdell, Wilmington Calif., Woman's Medical College, Chicago, 1884, aged 86, died, April 1, of myocarditis and hypostatic pneumonia

William Williams, Herndon, Ky., Louisville (Ky.) Medical College, 1872 Civil War veteran, aged 87, died, March 31, of paralysis of the throat.

George W Kernodle, Washington D. C. College of Physicians and Surgeons, Baltimore, 1886, aged 72, died May 2, of pneumonia.

Howard C Hart, Russiaville, Ind. Eclectic Medical Institute, Cincinnati, 1904 aged 56, died, May 10, of diabetes mellitus and paralysis

Joseph P Esch Daytona Beach Fla., University of Wooster Medical Department, Cleveland, 1876, aged 84, died, May 9 of pneumonia

William E Morriss Fort Smith Ark. College of Physicians and Surgeons Keokuk, Iowa, 1887 aged 75, died, April 3, in a local hospital

John W Buehler, Prairie Du Sac Wis., Bennett College of Eclectic Medicine and Surgery, Chicago, 1886, aged 85, died April 3

Rufus Reed, Margate City, N. J., Hahnemann Medical College of Philadelphia, 1871, aged 92, died, April 1, of myocarditis

Raymond A Bissey Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1902, aged 55, died March 10

C K Campbell, Dover, Ark (licensed, Arkansas, 1903) aged 66, died, May 6, of myocarditis and chronic interstitial nephritis

Edward I Haight, Emmett, Mich. Detroit College of Medicine, 1903, aged 58 died, April 15, in Port Huron (Mich.) Hospital

Edward Stell Haines, Chester, Pa. Hahnemann Medical College and Hospital of Philadelphia, 1891, aged 61, died, March 3

James A. Dodson, Waukomis, Okla., University of Nashville (Tenn.) Medical Department, 1874, aged 87 died, February 23

Laurence Edward Wright, Chatsworth Calif., Harvard University Medical School, Boston, 1922, aged 35, died, April 5

John S Jackson, Beaver Falls Pa., Baltimore University School of Medicine, 1886, aged 80, died May 2, of arteriosclerosis

Joseph Wilson Bartlett, Nashville, Tenn. University of Nashville Medical Department, 1905, aged 61, died, February 25

William Anson Powell, Los Angeles College of Physicians and Surgeons, Keokuk, Iowa, 1884, aged 82, died, April 6

Herman E Boice, Farmington Mich., Jefferson Medical College of Philadelphia 1899 aged 56, died, May 9, of heart disease.

Jefferson D Funderburk, Lancaster S. C. College of Physicians and Surgeons, Baltimore 1889, aged 71, died in March

James H Wheelless Thebes Ill. College of Physicians and Surgeons, Keokuk Iowa, 1881 aged 83, died, March 26

William Thomas Courtwright, Sedan, Kan. Medical College of Ohio, Cincinnati, 1886 aged 68 died, March 14

Zeno Green Logan, Tooele, Utah, University of Louisville (Ky.) School of Medicine, 1907 aged 54 died, April 8

Charles Frederick Dietz, Neola, Iowa, Medical Department of Omaha University, 1897, aged 68, died, April 21

John W Daniel, Franklin Ga., University of Louisville (Ky.) School of Medicine, 1873 aged 83, died April 18

John N Sebastian, Louisville, Ky., University of Louisville School of Medicine, 1899, aged 58, died March 5

John D Jackson, Pocatello Idaho Starling Medical College, Columbus, Ohio, 1887, aged 76, died March 12

Cale W Coe, Redlands Calif. Starling Medical College Columbus Ohio, 1888 aged 71, died, February 9

John Benjamin Owens, Rock Hill S. C., Atlanta (Ga.) Medical College, 1892 aged 65, died March 12

William Aaron Gibson, Jr., Thomson, Ga., Atlanta Medical College, 1915, aged 40, died, February 27

Abram Hassell King, Chestnut Mound Tenn (licensed, Tennessee, 1889), aged 83, died, February 16

Stephen E Smith, Topeka, Kan., Kansas Medical College Topeka 1893 aged 65, died, March 25

Joseph John Mahady, Brooklyn, Baltimore Medical College, 1893 aged 65, died, February 10

William F Gann, Columbus Ga. Louisville (Ky.) Medical College, 1888, aged 80, died March 24

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States
Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

Osmo Kaolin—Gabriel J. Fajardo New York Composition Clay For inflammation swelling etc. Fraudulent therapeutic claims.—[N J 17935 June 1931]

Gunn's Antiseptic—Merrick Medicine Co. Waco Texas. Composition Sulphuric acid (18 per cent) small quantity of a magnesium compound traces of carbon bisulphide and volatile oils with alcohol and water (cereal cure-all) Fraudulent therapeutic claims.—[N J 17936 June 1931]

U Ta Ka Indian Tonic—National Medicine Co. Nashville Tenn. Composition Essentially epsom salt extracts of plant drugs including a laxative drug sodium benzoate glycerin sugar and water. Fraudulent therapeutic claims.—[N J 17945 June 1931]

Alexander's Lung Healer—Smith Kline & French Philadelphia Composition Chloroform menthol spearmint oil extracts of plant drugs alcohol sugar and water. Fraudulent therapeutic claims.—[N J 17949 June 1931]

Mel Maroba—Sharp and Dohme Baltimore Composition Essentially potassium iodide (18.5 grains to the fluid ounce) resins tannins reducing sugar alcohol (17.7 per cent) and water. For syphilis rheumatism etc. Fraudulent therapeutic claims.—[N J 17952 June 1931]

Cassapine—Leadheater Drug Corp. Alexandria Va. Composition Essentially mineral oil with small amounts of thymol eucalyptol and the oils of camphor pine needle and cinnamon. For catarrh tuberculosis, etc. Fraudulent therapeutic claims.—[N J 17956 June 1931]

Anti Adenitis—Anti Adenitis Co. Hampton N. H. Composition Essentially sulphonated bitumen eucalyptol menthol a small amount of soap and water. For pneumonia etc. Fraudulent therapeutic claims.—[N J 17957 June 1931]

Perry Davis Vegetable Painkiller—Chas. L. Husking and Co. New York Composition Essentially camphor red pepper myrrh alcohol and water. Fraudulent therapeutic claims.—[N J 17958 June 1931]

Lafayette's Cod Liver Oil with Malt and Hypophosphites—Hance Bros and White Philadelphia Composition Essentially calcium potassium sodium iron manganese and phosphorus compounds, sugar alcohol and water with a small amount of cinchona alkaloids. Worthless as a source of vitamins A and D. Fraudulent therapeutic claims.—[N J 17961 June 1931]

Rexall Grippe Pills—United Drug Co. Boston Composition Essentially salicylic acid cinchona alkaloids red pepper and aloin. Fraudulent therapeutic claims.—[N J 17963 June 1931]

Smith's Specific Compound—Texatone Medicine Co. Enid Okla. Composition Essentially epsom salt with a small quantity of salicylic acid extracts of plant drugs and water. Blood purifier. Fraudulent therapeutic claims.—[N J 17971 June 1931]

Smith's King of All Pain—Texatone Medicine Co. Enid Okla. Composition Essentially petroleum oils and nitrobenzene. Fraudulent therapeutic claims.—[N J 17971 June 1931]

Tex A Tioe Ointment—Texatone Medicine Co. Enid Okla. Composition Petrolatum (97.4 per cent) and minute quantities of menthol and cinchonidine. For catarrh skin troubles etc. Fraudulent therapeutic claims.—[N J 17971 June 1931]

McCormick's Cold and Pain Salve—McCormick and Co. Inc. Baltimore Composition Essentially petrolatum with menthol and oils of camphor pine and thyme. Fraudulent therapeutic claims.—[N J 17973 June 1931]

Q 623—Loewy Drug Co., Inc. Baltimore Composition Essentially sodium salicylate baking soda and water. For rheumatism etc. Fraudulent therapeutic claims.—[N J 18028 July 1931]

Campbell's (James P.) Safe Arsenic Complexion Wafers—McCullough Drug Co. Cincinnati Composition Starch and a small quantity of arsenic. Fraudulent therapeutic claims.—[N J 18031 July 1931]

Clay Pine—Clay Pine Products Co. Columbus Ohio Composition Clay tar and water. For pneumonia etc. False claims for composition and fraudulent therapeutic claims.—[N J 18040 July 1931]

Stretch's Balsam Wild Cherry and Horehound—Joseph D. Blanth Estate Trenton N. J. Composition Extracts of wild cherry menthol methyl salicylate chloroform alcohol sugar and water. For coughs etc. Fraudulent therapeutic claims.—[N J 18041 July 1931]

Livingston's Regenerator—Livingston Medicine Co. Griffin Ga. Composition Epsom salt a laxative plant drug alcohol water and flavoring. Cure-all. Fraudulent therapeutic claims.—[N J 18043 July 1931]

Cherry's Famous Salve—William E. Cherry Trenton N. J. Composition Essentially a lead salt of an organic acid fatty oils and camphor. Fraudulent therapeutic claims.—[N J 18044 July 1931]

Resor Bisol—Burrough Bros. Mfg. Co. Baltimore Composition Essentially resorcinol a bismuth compound beta naphthol salicylic and gallic acids. For stomach disorders. Fraudulent therapeutic claims.—[N J 18045 July 1931]

Neutrone 99—The Kells Co. Inc. Newburgh N. Y. Composition Sodium salicylate (about 7 per cent) potassium iodide (0.2 per cent) a small quantity of an iron compound colchicum laxative drugs alcohol and water. For rheumatism etc. Fraudulent therapeutic claims.—[N J 18048 July 1931]

Kinoloids—Georgian Pharmacal Co., Atlanta Ga. Composition Quinine boric acid an iodine compound and cocoa butter. For female troubles. Fraudulent therapeutic claims.—[N J 18049 July 1931]

Deimar's Rheumatic Remedy—Glyza Chemical Co. Washington D. C. Composition Potassium iodide (7½ per cent) with small quantities of an arsenic compound a salicylate, other organic matter alcohol (42 per cent) and water. Fraudulent therapeutic claims.—[N J 18179 October 1931]

Halls' N T Iron and Nux Tonic—National Health Laboratories Scotland Neck N. C. Composition Epsom salt (23.2 per cent) ferrous chloride (0.5 per cent) a small quantity of strychnine a trace of formaldehyde and water. Fraudulent therapeutic claims.—[N J 18180 October 1931]

Laos (Samuel H. P.) Lithentriplic—S. H. P. Lee Co. Inc. New York Composition A plastic mass containing 46 per cent soap with potassium nitrate (5.3 per cent) potassium bicarbonate (10 per cent) juniper and other oils a small quantity of an iron compound and water. For kidney stone, gall-stones, diabetes etc. Fraudulent therapeutic claims.—[N J 18181 October 1931]

Gonolin—Lipoidal Laboratories, Inc. New York Composition Iodide phosphate a magnesium compound and extracts of plant drugs. For gonorrhea. Fraudulent therapeutic claims.—[N J 18183 October 1931]

Ac Ac—Approved Formulas Corp. Birmingham Ala. Composition Essentially aspirin acetanilid caffeine glycerin alcohol and water. For influenza pain etc. Fraudulent therapeutic claims.—[N J 18187 October 1931]

Trusler's Subacute Rheumatic Tablets—Kalmos Chemical Co. Cincinnati Composition Sodium salicylate and a laxative plant drug coated with calcium carbonate and iron oxide. Fraudulent therapeutic claims.—[N J 18192 October 1931]

Creta Methyl—Girard Pharmacal Co. Philadelphia Composition Clay 65 per cent with petroleum oil glycerin and methyl salicylate. For rheumatism inflammation etc. Fraudulent therapeutic claims.—[N J 18196 October 1931]

Brater's Asthma Powder—John K. Brater New York Composition Ground atramoum leaves with potassium nitrate. Fraudulent therapeutic claims.—[N J 18197 October 1931]

Seelye's Laxative Cold and Headache Tablets—A. B. Seelye Medicine Co. Abilene Kans. Composition Acetanilid extracts of aloe cinchona and red pepper. Fraudulent therapeutic claims.—[N J 18200 October 1931]

Seelye's Wasa Tusa—A. B. Seelye Medicine Co. Abilene Kans. Composition Alcohol ammonia sassafras oil small quantities of chloroform ether and red pepper. For rheumatism etc. Fraudulent therapeutic claims.—[N J 18200 October 1931]

Vitalox—Chemicals and Drugs Inc. Baltimore Composition Caffeine salicylic and benzoic acids licorice wild cherry a laxative drug strychnine valeric acid volatile oils alcohol and water. Adulterated and misbranded. Falsely represented as containing vitamin D.—[N J 18203 October 1931]

Abell's Formalde Balm—Home Remedy Co. South Haven Mich. Composition Essentially petrolatum with 1 per cent of volatile oils including eucalyptus and menthol. No formaldehyde present. For influenza hay fever etc. Fraudulent therapeutic claims.—[N J 18206 October 1931]

Astyptodyne Healing Oil—Astyptodyne Chemical Co. Wilmington N. C. Composition Essentially pine oil. For rheumatism etc. Not antiseptic or germicidal as claimed. Fraudulent therapeutic claims.—[N J 18209 October 1931]

Brame's Vapomentha Salve—R. M. Brame and Sons North Wilkesboro N. C. Composition Camphor menthol and eucalyptol in petrolatum. For pneumonia croup hay fever etc. Fraudulent therapeutic claims.—[N J 18211 October 1931]

Insurol—Deutsche Vital Gesellschaft Berlin Germany Composition Tablets containing yeast glandular tissue lecithin and lithium salicylate. For diabetes. Fraudulent therapeutic claims.—[N J 18212 October 1931]

Aromanna—Holdstein Drug Co. Paulsboro N. J. Composition Aloe licorice, baking soda an antimony compound a small quantity of salicylic acid with anise oil menthol sugar alcohol and water. Cure all. Fraudulent therapeutic claims.—[N J 18213 October 1931]

Bull's Sarsaparilla Compound—John D. Park and Sons Co. Cincinnati Composition Potassium iodide with small quantities of extracts of plant drugs sugar alcohol and water. For scrofula skin eruptions etc. Fraudulent therapeutic claims.—[N J 18218 October 1931]

Runners Cold Breakers—C. H. Griest Co. Wheeling W. Va. Composition Acetanilid cinchonine sulphate and camphor. False statement as to acetanilid content. Fraudulent therapeutic claims.—[N J 18223 October 1931]

Runners Old Fashioned Sarsaparilla Compound—C. H. Griest Co. Wheeling W. Va. Composition Podophyllum senna licorice potassium iodide (3.6 grains to fluid ounce) alcohol and water. Blood purifier. Fraudulent therapeutic claims.—[N J 18224 October 1931]

Runners' R R R Rheumatic Remedy—C H Griest Co. Wheeling W Va. Composition Sodium salicylate (28½ grains to fluid ounce) extracts of plant drugs a trace of alcohol and water. Fraudulent therapeutic claims.—[N J 18224 October 1931]

Urle O—E. C MacKallor Drug Co. Bioghamton N Y. Composition Sodium salicylate (28 grains to the teaspoonful) potassium iodide extracts of plant drugs alcohol and water. For rheumatism etc. Fraudulent therapeutic claims.—[N J 18302 January 1932]

Ingodine Tablets—Govett, Ltd. Long Island City N Y. Composition Extracts of plant drugs and iodine. For high blood pressure rheumatism etc. Fraudulent therapeutic claims.—[N J 18303 January 1932]

Tru Ade—Larweh Medical Co. Fort Wayne Ind. Composition Petrolatum lard camphor and a small quantity of menthol. Cure-all. Fraudulent therapeutic claims.—[N J 18305 January 1932]

Rice's Salve—Rice Chemical Co. Greensboro, N C. Composition Petrolatum, camphor menthol eucalyptol and turpentine. For pneumonia etc. Fraudulent therapeutic claims.—[N J 18306 January 1932]

Novopin—Quest and Co. New York. Composition Essentially a volatile oil such as pine needle oil (88 per cent) and baking soda. For nervous disorders etc. Fraudulent therapeutic claims.—[N J 18310 January 1932]

Nex Ri Tis—Chester G Adcox Co. Troy, N Y. Composition Sodium salicylate (277 grains to tablet) methenamine calcium carbonate a magnesium compound and small quantities of plant drugs and sugar. For rheumatism neuritis etc. Fraudulent therapeutic claims.—[N J 18311 January 1932]

Kelsey Ichthyl Suppositories—Southport Chemical Co. Inc. New York. Composition Essentially cocoa butter with ammonia and sulphur compounds. For piles female disorders etc. Fraudulent therapeutic claims.—[N J 18313, January 1932]

Pierre Cartier's Medicine—Bay State Drug Co. Palmer Mass. Composition An emulsion of cod liver oil (23 per cent) alcohol (15 per cent) invert sugar (37 per cent) with water and gum. General tonic. Fraudulent therapeutic claims.—[N J 18314 January 1932]

Huff's Old Reliable Sore Throat Remedy—Huff Bros. and Co. Pittsburgh. Composition Essentially chloroform iron chloride a small quantity of extracts of plant drugs with glycerin alcohol and water. Chloroform content misstated. Fraudulent therapeutic claims.—[N J 18317 January 1932]

Lincoln Tea—Fort Wayne Drug Co. Fort Wayne Ind. Composition Cut and powdered drugs including senna couch grass staranise camomile flowers and coriander seed. Liver and kidney disorders etc. Fraudulent therapeutic claims.—[N J 18319 January 1932]

Quinseptikons—Tablax Co. New York. Composition Suppositories containing salicylic acid (0.9 per cent) boric acid (13.5 per cent) quinine hydrochloride (5.3 per cent) and theobroma oil. As a vaginal prophylactic, for local infections etc. Fraudulent therapeutic claims.—[N J 18324 January 1932]

Gen Lax—Mobile Drug Co. Mobile Ala. Composition Essentially iron (ferrie) sulphate epsom salt hydrochloric acid and nitric acid potassium acetate and water. Cure-all. Fraudulent therapeutic claims.—[N J 18328 January 1932]

Kettner's Excelsior Blood Purifier—Composition Potassium carbonate potassium nitrate a laxative plant drug alcohol and water. Fraudulent therapeutic claims.—[N J 18332 January 1932]

Livingston's Re Gem (Regenerator)—Livingston Medicine Co. Griffin Ga. Composition Essentially epsom salt a laxative plant drug alcohol (11.8 per cent by volume) and water. Cure-all. Fraudulent therapeutic claims.—[N J 18337 January 1932]

Livingston's Golden Catarrh Balm—Livingston Medicine Co. Griffin Ga. Composition Carbolic acid camphor menthol and eucalyptol in a mixture of petrolatum and paraffin. Fraudulent therapeutic claims.—[N J 18339 January 1932]

Baodisine—A Renkert and Co. Memphis Tenn. Composition Small quantities of baking soda horax camphor menthol and alcohol in water. Not antiseptic. Fraudulent therapeutic claims.—[A J 18343 January 1932]

Alco Pain Killer—Alertox Inc. Atlanta Ga. Composition Kerosene ether, methyl salicylate and oils of mustard turpentine and camphor. Fraudulent therapeutic claims.—[N J 18344, January 1932]

Livingston's Root and Herb Tea—Livingston Medicine Co. Griffin Ga. Composition Ground plant drugs including bearberry senna buck thorn coriander fennel mullein and guaiac. Blood purifier. Fraudulent therapeutic claims.—[N J 18348 January 1932]

Search Warrant Liniment—Livingston Medicine Co. Griffin Ga. Composition Essentially alcohol ammonia capsicum oleoresin oil of camphor and water. Alcohol content wrongly declared. Fraudulent therapeutic claims.—[N J 18349 January 1932]

Livingston's Speal Inliverator—Search Warrant Liniment Co. Griffin Ga. Composition Essentially epsom salt, with senna alcohol (15.2 per cent by volume) sugar and water. Tonic. Alcohol content wrongly declared. Fraudulent therapeutic claims.—[N J 18351 February 1932]

Le Sleur's Syrup of Tar and Cod Liver Extract—Nemock Specialty Co. Somerville Mass. Composition Chloroform tar menthol sugar alcohol and water. Fraudulent therapeutic claims.—[N J 18354 February 1932]

Septigyn Tablets—N and S Co. Dallas Tex. Composition Zinc phenolsulphonate (48.8 per cent) sodium phenolsulphonate (21.4 per cent) copper phenolsulphonate (3.3 per cent) Glauber's salt (18.7) and milk sugar. For gonorrhea etc. Fraudulent therapeutic claims.—[N J 18356 February 1932]

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

TRICHOMONAS VAGINALIS

To the Editor—Do you think it is probable or possible that infection with *Trichomonas vaginalis* can be transmitted through bathing in a swimming pool in which a person known to have leukorrhea and pruritus caused by this parasite has been a frequent bather? The water of the pool has been chlorinated and an attempt is made to keep the concentration between 2 and 4 parts per million of free chlorine. The laboratory tests have consistently been negative for *Bacillus coli* in 10 cc fermentation tubes. What is the most efficacious treatment for *Trichomonas vaginitis*?

WILLIS P. BAKER, M.D. Santa Ana Calif

ANSWER—It is impossible for women to contract an infection due to *Trichomonas vaginalis* through bathing in a swimming pool because even ordinary tap water, untreated with chlorine or any other chemical destroys these organisms. *Trichomonas vaginalis* apparently lives in symbiosis with other organisms in the vagina and it can be grown only in certain special mediums. It seldom survives even when transplanted from the vagina of one woman to that of another.

There are many ways of treating the vaginitis associated with the *Trichomonas vaginalis*. Unfortunately whereas immediate relief can usually be accomplished in almost every instance, there are many recurrences. The treatment suggested by Greenhill (*THE JOURNAL* May 30, 1931, p 1862) is as follows:

The vagina is thoroughly scrubbed with gauze or cotton saturated with tincture of green soap (liniment of soft soap L. S. P.). All the vaginal folds are smoothed out and every part of the mucosa is scrubbed. The scrubbing is one of the most important steps in the treatment and it is usually persisted in until slight bleeding is noted in the vaginal mucosa. Bleeding generally occurs because the mucosa in these cases is friable. The soap is washed out with tap water or with mercuric chloride and the vagina is dried thoroughly. A speculum is inserted into the vagina and hexylresorcinol is instilled into the vagina and applied all over the vaginal wall in the vault of the vagina and on the cervix. A tampon saturated with half or full strength glycerin is then inserted high up into the vaginal vault. A second, dry tampon is inserted to prevent the escape of glycerin on the patient's clothing. Hexylresorcinol is applied to the vulvar and anal regions and the patient is instructed to remove the tampons after twenty-four hours. The string of the second tampon has a knot tied in it so that the patient may know that this tampon is to be pulled out first. After removal of the tampons a douche of tincture of green soap is taken. The treatment outlined is repeated every second day for at least three times. The patient takes a green soap douche on the mornings between treatments but not on the mornings she is to receive a treatment. A douche is not taken on the morning of a treatment because it is desirable to see how much discharge there is and also because hanging drop examinations are made at that time. Treatment is continued until hanging drops on two successive visits fail to show the trichomonas. However the patient is advised to take a 0.5 per cent lactic acid douche daily for about two weeks after treatment is discontinued. The purpose of the lactic acid douche is to attempt the reestablishment of a normal bacterial flora in the vagina.

A matter of great importance but unpleasant to discuss is the cleansing of the anus after a bowel movement. To accomplish the latter most women use an upward sweep toward the vagina and urethra but this may produce reinfection if the causative organisms come from the rectum. The patients are instructed to use a sweeping motion directed away from the vagina and toward the sacrum. The significance of this method of cleansing the anal region should be impressed on the patient.

Since recurrences of the troublesome discharge occur in a certain proportion of cases and since these frequently manifest themselves immediately after a menstrual period it is advisable to reexamine patients just before and just after a menstrual period. If organisms are found, a course of treatments should again be given.

"URODONAL"

To the Editor—Please let me know if you have any information on the remedy called Urodonal made by J. L. Chatelein of France and distributed in this country by George J. Wallau Inc. I should like to know approximately what the chemical constituents are.

M D Louisiana

ANSWER—Urodonal is one of the patent medicine variety of products which the promoters have the effrontery to sell to the medical profession. In 1915 the Council on Pharmacy and Chemistry reported on Urodonal and at that time showed the foolishness of the chemical formula then given. The Council stated that it was improbable that such a substance was a definite chemical compound. The firm submitted no evidence to substantiate the claims. Even at that time the firm was not consistent in statements of composition since it virtually admitted that the product was a mixture. 'Urodonal' is a granular effervescent preparation based on methylglyoxalidine [Lysidine], guanate of diethylene-diamine [Sidonal]

and hexamethylene-tetramine [Formin, urotropine]" Mystery was added by the mention of the undefined 'special products' in the following "The fact of combining these two salts [Insidin and sidonal] in Urodonal, in strictly determined proportions and in the presence of special products, gives this preparation very considerable power in dissolving uric acid" The Council held that Urodonal was marketed under inconsistent statements of composition and with exaggerated therapeutic claims that the name was nondescriptive and the mixture unscientific.

March 24, 1932 the United States federal government officials seized a shipment of Urodonal alleged to have been shipped by George J. Wallau (Inc.) of New York, charging misbranding in violation of the food and drug act. April 26 1932, no claimant having appeared for the property judgment of condemnation and forfeiture was entered. In the libel it was alleged that the article was misbranded in that certain statements appearing in the circular accompanying the article regarding its curative or therapeutic effects, were false and fraudulent, since it contained no ingredient or combination of ingredients capable of producing the effects claimed. The chemist for the government analyzed the stuff and reported that it consisted essentially of methenamine (4 per cent), sodium phosphate (18 per cent), sodium bicarbonate tartaric acid and a small proportion of sugar. (Notice of Judgment Under the Food and Drugs Act United States Department of Agriculture, Food and Drug Administration December, 1932, number 19477.)

EFFECTS OF XYLENE TREATMENT OF BURNS

To the Editor—Please give me the physiologic effects of xylene if applied to a raw area such as might be expected in the removal of grease and ointments applied to burns in preparation for tannic acid. In the many experiments trying to show the cause of death from burns have there been any in which a large area of skin is removed surgically and aseptically that show the results on the organism of loss of skin function only? If so what were the results? Please omit name.

M D Texas.

ANSWER—Xylene is a satisfactory agent for the removal of ointments from burned areas, and it apparently does not produce any change in the tissues. At times it causes a mild hyperemia of the skin. A disturbance of one or another of the various functions of the skin—namely respiration excretion, temperature regulation and sensitization—has been made the basis of theories explaining the clinical course that follows extensive burns. It may be possible to use the experimental work of Harrison and Blalock as a basis for determining the effect of the removal of large areas of skin. No direct reference to experimental work of the type mentioned is available. The bibliography attached to the article by E. C. Davidson (*Surg. Gynec. & Obst.* 41:202 [Aug.] 1925) refers to the principal experimental work that has been done along this line.

INDICATIONS FOR REMOVAL OF DEAD FETUS

To the Editor—A Puerto Rican woman aged 21 with a full term pregnancy was seen in active labor. She had irregular pains three days prior to admission the pains becoming regular the day before admission and at the time of admission being moderate and occurring every ten minutes. Rectal examination revealed the cervix three fingers dilated the membranes intact the head floating. The patient had not felt fetal movements for three days nor could the fetal heart be heard. This was her second pregnancy. The first pregnancy was terminated by abdominal section because of contracted pelvis (a living male child being delivered) two and a half years before. Pelvic measurements were interspinous 23.0 cm. intercrural 24.0 cm. external conjugate 15.5 cm. transverse of outlet, 8.5 cm. diagonal conjugate 11.5 cm. She had been receiving prenatal care and another section was contemplated. A section and sterilization were performed and a macerated dead fetus was delivered. At the time of the patient's labor every examiner was satisfied that the fetus was dead. In view of such facts as the dead fetus and the cervix dilated three fingers would not a craniotomy have been the procedure of choice? The only objections against craniotomy given were 1. Once a section always a section 2. Danger of uterine rupture. If a craniotomy was not indicated in this case in what condition would it be indicated? Please omit name.

M D New York.

ANSWER—As a general rule one should not do cesarean section when the baby is dead and macerated. If the ovum is infected a Porro operation might be considered but more often it is safer to deliver from below, especially if the cervix already is taken up and admits three fingers. Rarely does one perform a cesarean section with abruptio placental and placenta praevia—even if the baby is dead.

If there is no infection sufficient dilatation can usually be produced by means of a metrectomy, so that embryotomy can be performed. The danger of rupture of the uterus here is not sufficient to justify another cesarean section.

Most authorities do not subscribe to the dictum 'once a cesarean always a cesarean.' Therefore such cases may be

left to nature. However, it is good practice, as soon as the cervix is dilated, to empty the uterus by craniotomy if the fetus is dead.

In the case reported, the tying off of the tubes leaves the family with only one child, which is always unfortunate and many women regret the sterilization when the only child has died.

MILK IN THE DIET AND DENTAL CARIES

To the Editor—Will you please send me what information you have on the experiment conducted at Mellon Institute regarding the effect of lactic acid in milk and other foods on decay in children's teeth. I have been told by a dentist in Milwaukee that the results of such a research problem at Mellon's were published in an authentic health magazine some time ago and I am eager to know what was the purpose of this research, how it was conducted and what were the results. In all the research material to which I have access such as that of Dr. Henry Sherman, Dr. E. V. McCollum and Dr. Lydia J. Roberts all reaction toward the use of milk in the diet of growing children is favorable. So I am wondering if there is some late material that questions the advisability of a daily quart of milk per child. I will deeply appreciate hearing from you in this matter, and I will thank you for the information.

Milwaukee.

ANSWER.—The report of the investigations to which reference is made is published in full in the *Journal of Dental Research*, 12:759. It consists of an elaborate effort to determine the cause and nature of dental caries from the standpoint of the chemist, the bacteriologist and the histologist. Its purpose is to evaluate the importance of two schools of thought regarding the primary cause of dental decay. The older school is represented by those who believe that the exciting cause lies in local environmental factors, and the younger by those who believe that it lies in the field of nutrition. The literature on this subject is reviewed and discussed.

The work was carried out in three parts: (a) a comprehensive study of the effect of acids on enamel, (b) a study of the effects of variations in the saliva on the progress of dental caries, and (c) a bacteriologic survey of carious enamel processes.

While the work is not final, it is stated in the conclusions that local environmental conditions are the main factors in the active causation of decay of fully erupted enamel," and that "deficient diet and defective nutrition by being responsible for the construction of teeth more susceptible to the action of acids of fermentation are the most important factors during the development of the teeth." They add that "improper diet and defective nutrition by being responsible for a salivary environment low in content of calcium phosphate are of some, though minor importance as a predisposing factor in caries of the enamel."

Nothing in this report should disturb those who have been advocating the use of a quart of milk daily for children. In the second part of the conclusions, just quoted, the authors admit the importance of good diet and nutrition during the development of the teeth. Since the development of the teeth is not completed until the twentieth year or thereabouts, and since the authors have thus far failed to prove beyond a reasonable doubt that the lactic acid bacillus is the exciting cause of caries, and since they admit that notwithstanding the campaign of cleanliness alkalization and gum massage waged for many years caries and other dental disorders have continued, there could be only the slenderest argument for eliminating milk from the diet of a child.

NAUSEA OF PREGNANCY—LATE EFFECTS OF ABORTION

To the Editor—A woman aged 24 is seven weeks pregnant. Nausea at first mild and infrequent set in between the third and fourth weeks. Now it is more or less constant and often gets worse in the evening. Vomiting with short relief occurred only two or three times. Needless to say the patient is much distressed she feels weak and not herself. About a year ago she had an induced abortion at two months. Since then until the present pregnancy her menses have been scanty and not as red and thick as before the abortion. Will you please comment on the relationship between the abortion the scantiness of menstruation and the present nausea. Belching is another prominent symptom which I could not control. What should be done for the eructations and the nausea? Please omit name.

M D New York.

ANSWER—Induced abortion even when performed under proper aseptic precautions, may lead to disturbances in the sexual functions. Not only may scanty menses occur after such operations but also the reverse, profuse hemorrhages. Other complications that occur after induced abortions are inflammation of the internal genitalia, sterility, spontaneous miscarriages extra-uterine pregnancy, persistent amenorrhea infections of the urinary tract, and difficulties in subsequent labors.

There is most likely no connection between the abortion and the nausea in the present pregnancy, because about 50 per cent of all women are nauseated in the early months of gestation. Likewise, belching is a common symptom in pregnancy. In order to overcome the nausea the patient should not attempt to eat the usual three meals a day but should take small amounts of solid food, especially starches and sweets every two hours. If part of the food is vomited, more should be eaten immediately. Water should not be taken with these small meals but in the intervals between them. An additional aid is to have the patient eat a few crackers or dry toast in the morning about half an hour before getting out of bed. Belching and heartburn, which are frequently associated may sometimes be prevented by drinking a glass of milk and cream mixture a few minutes before meal time. The fat in the cream and milk prevents the secretion of acid in the stomach. However, in the presence of actual heartburn the fat may aggravate the condition. The usual remedies for belching and heartburn are half a glass of water containing half a teaspoonful of sodium bicarbonate, a teaspoonful of magnesia magma or two or three soda mint tablets.

FALSE POSITIVES WITH KAHN TEST

To the Editor—A man aged 69 married whose past history is irrelevant to venereal disease about six months ago noticed gradual swelling of the tongue which at present is 50 per cent larger than normal is very red and is covered with mucopurulent nodules. Tendon reflexes are present. There is no Romberg sign no positive Babinski reflex, and the pupils are not of the Argyll Robertson type. He was referred to the hospital laboratories Dec. 1 1932. His height is 5 feet 5 inches (165 cm.) his weight 134 pounds (61 kg.). A Kahn test gave a four plus. In spite of ten intravenous injections of 0.45 Gm. of neoarsphenamine and seven intramuscular injections of a bismuth compound no change has occurred in the buccal lesion and the pain in the mouth is increasing to a point at which narcotics will be necessary. No dark field examination has been made. Will you kindly advise me whether there are other conditions that give a positive Kahn test? If so what conditions should be considered? Please omit name. M D Illinois.

ANSWER—It is extremely rare to obtain false positives with the Kahn test. An illustration of the specificity of this method is found in a recent report that it is not influenced by malaria—a condition wherein other serologic tests occasionally give false positives (Smith, C R. *J Lab & Clin Med* 18:396 1933). In all likelihood however, the tongue condition referred to is not of a syphilitic nature. It is unfortunate that the presence of syphilis in a patient is often rendered responsible for all pathologic conditions in that patient. It should be recalled in this connection that Belote (*THE JOURNAL* June 1 1930, p 1985) has emphasized that more than 30 per cent of carcinomas of the tongue have a syphilitic background.

REPEATED MISCARRIAGES AND STERILITY

To the Editor—A woman aged 26 has had three miscarriages has no children and craves having a family of three or four. She was born in Russia and was 3½ years of age when she came to the United States. Her father is living her mother died in 1911 from cancer of the breast. Three brothers are living. Twin brothers died at premature birth. She has four sisters living all of whom have children. Two brothers married and have children. The patient married at the age of 18 and has had three pregnancies. The first child, premature at six months lived five hours the second child premature at seven months, lived five days the third pregnancy resulted in the premature birth last November at five and one-half months of a child that lived one hour. She has been examined at two different clinics in the larger cities and everything has been found normal even to the Wassermann tests. The last time was in August 1932 while she was carrying the last child and still nothing wrong was found. She has a good appetite sleeps well exercises regularly outdoors walking only does her regular housework and raises a garden each season. She is large of build and weighs nearly 157 pounds (71 kg.). Please omit name. M D North Dakota.

ANSWER—A history of repeated late miscarriages always arouses the suspicion of syphilis. A negative Wassermann test, even if repeated, does not always rule out syphilis. It is unfortunate that there were no autopsies made on the fetuses or microscopic studies of the placentas, because such investigations would definitely place the blame on syphilis or rule it out. In spite of the absence of physical signs of syphilis and the negative Wassermann test, it would be advisable to give the patient some injections of neoarsphenamine. This would do no harm and the general effect might help. It is assumed that the patient does not have any constitutional disorder such as anemur hypothyroidism or other disturbance of the glands of internal secretion or a focal infection, or a pelvic condition that might account for the premature termination of pregnancy. The husband should, of course, be carefully examined for evidences of syphilis and mild chronic poisoning such as that due to lead. Even if the physical examination of the husband is negative there still remains the possible explanation that for

some reason the spermatozoa cannot produce full-term children. If examination of the sperm reveals gross abnormalities, an attempt should be made to build up the husband's general physical condition. An important prophylactic measure is to have the patient remain in bed for a number of days at the time when menstruation would have occurred if she were not pregnant. The administration of thyroid often helps, especially in women with low basal metabolic rates.

TETANY AFTER THYROIDECTOMY

To the Editor—A woman aged 32 had a thyroidectomy performed six and a half years ago because of typical symptoms of hyperthyroidism. At the operation some of the parathyroid tissue was inadvertently removed. She remained in the hospital two weeks during which time she had attacks of tetany about every other day. She then went home where she continued to have these attacks and she returned to the hospital two months after operation. Here she received injections of parathyroid extract and calcium by mouth daily with a decrease in the number of attacks. She returned home where she continued to receive injections of parathyroid extract every other day for over a year. Six or seven months after operation her vision began to diminish owing to the development of cataracts in both eyes. From the time of the operation until now she has had attacks of tetany at frequent intervals. For the last two years she has been taking 20 grains (1.3 Gm.) of calcium lactate three times a day 20 drops of iosteroil daily and pills of ferrous carbonate daily. Occasionally ultraviolet therapy has been given. The Wassermann reaction is negative. The blood calcium has never been above 7.5 since the operation it averages 6.8. Blood counts average 78 per cent hemoglobin and 4 100 000 red blood cells. The basal metabolism rate Aug. 2 1932 was -24. The patient was therefore given synthetic thyroxine by mouth for twenty days ½ mg daily and thereafter every fourth day for two months with a rise in the basal metabolism rate to -17 and then to -5 (on December 5). Lately the attacks of tetany have been occurring about once a week. Can you suggest any further treatment in addition to that employed? Kindly omit name. M D Pennsylvania.

ANSWER—As to the medical treatment given in this case of postoperative tetany, much freer use of parathyroid extract (from 60 to 100 units daily) is to be suggested in view of the formation of cataracts and weekly tetanic seizures indicating 'missing' parathyroid function. (At times the serum calcium is not low in such a case.) Calcium and thyroid to be sure, can be given at the same time. By mouth, three times a day after eating, 7.8 Gm (2 drachms) of a mixture consisting of calcium gluconate, 125 Gm (4 ounces), disodium phosphate, 30 Gm (1 ounce), sodium bicarbonate sufficient to make 250 Gm (8 ounces). In addition thyroid extract, 0.03 Gm (one-half grain) three times a day.

In several severe cases of tetany following thyroidectomies parathyroid glands have been transplanted material obtained at parathyroidectomies on patients with (hyper)parathyroidism being used, even adenomatous glands may be used. For instance, one patient who required up to 100 units of parathyroid extract daily for two or three years was freed from tetany for eight months following transplantation. Then a recurrence was again treated with a similar result for six months. The recurrences were much milder and did not disable the patient any more. In other cases from good to fair results have been accomplished freedom from tetany for from four to eight months with milder recurrences of the disorder.

Further transplants of small pieces of boiled beef bone (3 by 2 by ½ cm.) under the skin of the chest (as recommended by von Oppel's clinic) have contributed to keeping the disturbed calcium metabolism in tetany in equilibrium.

FREQUENT SPONTANEOUS ABORTIONS AND STERILITY

To the Editor—A woman aged 40 highly active in business has had several abortions at two or three months with the one pathologic specimen examined showing only a cyst instead of a well formed fetus. After thorough gynecologic study the only cause suggested was that of uterine fibroids not definitely found but suspected because of an indefinite uterine outline and fleeting pains in the rectum often darting and knife-like and sometimes slight cramps there occurring almost daily and especially during the abortions. If that is the cause of the abortions, is there any uterine sedative that might make possible a successful pregnancy? Would amylal if it should prove effective given over a period of three or four months in a mild dosage compatible with business in any way endanger the patient? Is there any reason to fear that such a pregnancy might result in an abnormal child? Please omit name and address. M D New York.

ANSWER—The specific cause of most spontaneous early abortions is unknown. Undoubtedly however, a defect in the development of the ovum either because of a disturbance in the ovum itself or because of some abnormality in the environment, is usually responsible for the early termination of pregnancy. Fibroids are frequently found in sterile women but whether they are the cause or the effect of sterility is still an unsettled question. They do not, however, often produce early

abortions. In the case cited the finding of a cyst without any fetus indicates that in this particular abortion the ovum failed to develop properly and was therefore expelled. It is unfortunate that a microscopic examination was not made of at least one ovum although in most instances even this kind of a study does not shed much light on the etiology. An undue irritability of the uterus due to a disturbance in its nervous mechanism may be responsible for repeated abortions, but this is difficult to prove. The pains described do not necessarily point to such a condition. Furthermore, drugs such as pituitary extract, ergot and quinine, which have a definite and often powerful stimulating effect on the uterus, nearly always fail to cause the expulsion of a normal gestation. Therefore, a drug administered as a uterine sedative will most likely be of little assistance in preventing habitual abortions. It is not advisable to give amniot over a period of months but, if it should be given, it would have no tendency to result in an abnormal child. A general tonic to build up the patient would be more effective. It is assumed that the patient has had a thorough physical examination to rule out a focal infection, a constitutional disorder such as anemia or a disturbance in the glands of internal secretion, particularly hypothyroidism or a local disturbance such as an acutely retroflected and adherent uterus. Syphilis is responsible for many cases of habitual abortion but very rarely for the early ones. It may be advisable to perform a curettement to make certain that there is no inflammation of the endometrium, although this is rare. The husband may be at fault because undoubtedly in some instances the spermatozoa are not capable of producing healthy, full term offspring. Mild chronic poisoning, such as that due to lead, may account for some of these cases.

FEVER OF UNKNOWN ORIGIN

To the Editor—A man aged 62 who had always lived in Minnesota and had always been well was suddenly taken ill seven and a half weeks ago with what was described as the flu consisting of intermittent high fever with severe chills. The temperature ranges from normal to about 104° F but has gone higher on a few occasions. There is no regularity in the type of the intermittence of the fever though the rises of temperature usually occur once daily sometimes oftener. The type of fever is such as might be seen in a severe pyemia. The chills occur every day or oftener in relation to the fever and are severe lasting from twenty minutes to as long as two hours. Physical examination reveals only a moderate tenderness over the liver with a slight enlargement of that organ. All other physical examinations have been negative on numerous occasions. Laboratory examinations have been as follows: The urine shows a moderate amount of albumin and a few hyaline casts. The hemoglobin is 62 per cent. The erythrocytes average 3,800,000. Differential counts have always been normal. A finding of importance in view of the fever is the fact that the leukocyte count has always been between 8,000 and 8,600 never higher. Blood smears examined for malarial parasites have several times been negative. The Wassermann reaction is negative. The Widal test is negative. The Pirquet test is negative. The state board of health reports that the blood is negative for undulant fever, typhoid, typhoid and paratyphoid A and B. Animal inoculation has not been reported on as yet. The mentality of the patient remains good. There has been no mental confusion except on one occasion and that passed off shortly. The patient is slightly depressed. The eye grounds are normal. There has been vomiting of bile or bile-stained contents on a few occasions but the appetite remains good. There has been no diarrhea. The patient sleeps well. Perspiration is profuse after the chills. The pulse ranges between 80 and 120 the rate of respiration between 15 and 20 or 22. Both the pulse rate and the respiration follow the temperature closely. When the temperature is normal the pulse is 80 and the respirations are 15. Would the negative Pirquet test rule out the diagnosis of miliary tuberculosis? When the temperature is normal the patient feels well and wants to get up. The normal leukocyte count should certainly cancel any diagnosis of infections of pus-producing organisms. Please omit name. M D Minnesota

ANSWER—An excellent summary of the subject of fever of unknown origin can be found in an article entitled "Fever of Unknown Origin," by Howard L. Alt and M. Herbert Barker (THE JOURNAL, May 10, 1930, p. 1457). As the authors point out many patients with fever of unknown origin are discharged without any diagnosis only to develop definite clinical conditions later on as malignant disease, endocarditis, tuberculosis, pyelitis, hepatic disease (abscess) and so on. The failure to find malarial parasites should be no bar against the administration of quinine. The authors believe that some of these patients harbor a "smoldering rheumatic infection." Occasionally a cortical renal lesion may not have broken into the tubules and pus will not appear in the urine. Such a patient was seen several years ago in whom pus appeared in the urine after he bent forward and backward several times at the suggestion of an attending urologist. Pyelonephritis may exist without much pain for several weeks before the formation of an abscess sufficient to give localizing symptoms. Conditions that must be looked for without giving any definite evidence are deep seated venous thromboses. A negative Pirquet test does not rule out tuberculosis.

Book Notices

The Common Cold with Special Reference to the Part Played by Streptococcal Pneumococci and Other Organisms By David Thomson and Robert Thomson. *Annals of the Pickett Thomson Research Laboratory* volume VIII. Published for the Pickett Thomson Research Laboratory London. Paper Price \$15 £3 3s Pp 738 with illustrations. Baltimore: Williams & Wilkins Company, London: Baillière Tindall & Cox 1932

This large volume is chiefly a review of the literature on the common cold. The authors do not believe that the common cold is a definite single disease caused by one organism but a group of diseases caused by several different species of organisms. They divide colds into three groups—bacterial, allergic, and possibly virus colds. Their fifteen years of "exceedingly careful" study of the bacterial flora of the respiratory tract in a limited number of persons during health and during colds led them to conclude that pneumococci, B influenzae, streptococci and M catarrhalis are definite primary causes of colds. They point out that Webster and Hughes and Clow in America have come to the same conclusion after careful research. There is abundant scientific proof they say, which shows that chill is an important predisposing cause of colds. The incidence of colds in a community immediately rises after a sudden spell of cold weather. The popular view that overcrowding indoors in stuffy atmospheres increases the chances of infection is also correct. Other predisposing factors are fatigue, damp clothing, bad ventilation, nasal obstruction, gastro-intestinal infections, and an inborn insusceptibility. Old clothes may harbor the infection. It is important to change damp clothing after finishing work or exercise, otherwise there is a chilling effect produced by evaporation. It is especially dangerous to go driving in an open automobile after perspiring. In preventing colds, the authors believe that the most important measure is to remedy defects in the nose, such as removal of adenoids and polypi, and removal of enlarged and unhealthy tonsils. Ultraviolet rays are excellent during the winter months in increasing resistance to colds. The authors emphasize cleanliness and the avoidance of crowded places during epidemics. One should also avoid patients in sickrooms and dust laden atmospheres. This volume is especially valuable for its bibliography as the authors have extracted information from about 2,000 research papers on the common cold.

Quantitative Clinical Chemistry Volume II Methods. By John P. Peters M.D. M.A. Professor of Internal Medicine Yale University School of Medicine and Donald D. Van Slyke Ph.D. Sc.D. Rockefeller Institute for Medical Research. Cloth Price \$10 Pp 957 with 95 illustrations. Baltimore: Williams & Wilkins Company 1932.

The review for volume I remarked that 'this monograph will take its place as the leading reference work for a summary of the information that has been published on the subject. The appearance of the companion volume, on laboratory methods, is awaited with interest'. Volume II maintains the high standard established in the first volume. The authors have not covered all of the laboratory methods of quantitative clinical chemistry, but those that were included in the book have been tested as far as possible by the authors or were such as would meet the critical standards set by the authors. Wherever possible a gravimetric, titrimetric, colorimetric or gasometric procedure with macro and micro forms has been presented. In view of Van Slyke's extensive experience with gasometric methods it is hardly surprising despite the original intentions of the authors to include one of the three general

methods of analytic chemistry, that a large portion of the book is devoted to gasometric methods.

The volume is more than a collection of analytic methods. The principles on which the methods for the determination of the various clinically important groups included in the book are based are discussed at the beginning of each chapter. The range of the book is shown by the material of the thirty-three chapters: general chemical technique, special biochemical technique, analyses of gas mixtures, carbon dioxide and oxygen tensions in alveolar air, respiratory metabolism, lung volume, gasometric methods for analysis of blood and other solutions, sugar, lipids, total and nonprotein nitrogen, urea, urinary ammonia, amino acids, uric acid, creatine and creatinine, lactic acid, acetone, acetoacetic acid and beta-hydroxybutyric acid, total organic acids, phenols, hemoglobin and its derivatives, proteins in urine, blood plasma and body fluids, blood volume, total base, sodium and potassium, calcium, magnesium, the pH of blood and urine, bicarbonate, titratable acid and acid-base excretion in urine, chloride, phosphorus, sulphur and an appendix. The arrangement follows quite closely that of the first volume. An ample bibliography follows each chapter.

Despite the uncertainty that all of the chromogenic material in blood is creatinine and creatine, the authors devote a chapter to methods for the determination of creatinine. This is justified by the authors because of the significance it has in nephritis, and also because of the possibility that the significance of the chromogenic matter may be clarified by future work. The appearance of this book is another indication of the trend of clinical chemistry from qualitative to quantitative methods. The methodology of the book is significant for teachers of biochemistry in medical schools.

Practical Anesthesia By the Anesthetic Staff of the Alfred Hospital Melbourne. With a foreword by F. H. McMechan A.M. M.D. Secretary General International Anesthesia Research Society. Monographs of the Baker Institute of Medical Research No. 1. Fyshkold. Price 10/6d. Pp 249 with 70 illustrations. New South Wales: Australasian Medical Publishing Company Ltd 1932.

This monograph is based on a series of lectures delivered to junior house officers of the Alfred Hospital at Melbourne and is published in seventeen chapters with two appendices. Although didactic and concise, the style is flowing and holds the reader's interest. While 168 references prove a wide acquaintance with the literature, the work is largely original and abounds with striking statements of fact well calculated to hold the student's attention. For example 'In the ordinary operation there are three persons, all of whom play parts of great importance, namely, the patient, the surgeon and the anesthetist. No one of these can be said to play a less or greater part than another, and each of them is, for the time, dependent on the other two. During the operation, the anesthetist still finds himself playing an important role.

Almost literally, he holds a life in his hands and those hands must never loosen their hold.'

In Australia, the ethyl chloride open ether sequence is the routine anesthetic. Ethyl chloride is acknowledged to be more dangerous even than chloroform, yet the advantages of convenience and portability are allowed to outweigh the greater safety of the nitrous oxide-oxygen-ether sequence so extensively used in America. Ether is administered by the drop method, with insistence on an open airway and freedom from cyanosis, which might well be followed in our own hospitals. Nitrous oxide and ethylene are both in use. 'Probably, in the average case one gas is as good as the other. Better relaxation is obtainable with ethylene. Nitrous oxide is definitely preferable in thyroid surgery'. Three methods of induction are recommended: (a) pure oxygen followed by pure nitrous oxide or ethylene, (b) delivery of the maintenance mixture from the start, (c) pure anesthetic gas to which oxygen is added as indicated. The recommendation is that the inexperienced anesthetist try all these methods and choose that which gives the best results in his hands. It would seem a wiser plan that the instructor elect the method and teach this technique to the student.

The advantages of premedication are listed as securing mental rest for the patient, securing safer and better anesthesia, mitigating the toxicity of local anesthetics, and lessening the secretion of mucus. Administration of sedatives in large doses to produce the condition termed "basal narcosis" is not recom-

mended except in the rare instances when such narcosis is clearly indicated. The full discussion of accidents and sequelae of anesthesia will be appreciated by the student.

The technic of spinal anesthesia is well described. Its use is restricted because of the difficulty of controlling or predicting the degree of subsequent circulatory and respiratory depression. The use of regional and local anesthesia is given in outline and reference made to more extensive studies of this topic.

The advantages of endopharyngeal anesthesia are discussed from the standpoint of the patient, who experiences a safe and even anesthesia, from the standpoint of the surgeon, who finds available a continuous anesthesia with a clear operative field, and from the standpoint of the anesthetist, who readily controls the depth of anesthesia maintained at a light and even level. Endotracheal anesthesia is covered in the longest chapter of the book. Endotracheal insufflation using ether, chloroform or the gaseous agents is discussed and its advantages are indicated. Endotracheal inhalation, by the methods of Flagg and of Magill is minutely described.

The work is ably introduced by the foreword of Dr. F. H. McMechan. It is completed by an index which occupies the last eighteen pages. Of the seventy illustrations sixty-five are original. The book is well printed and strongly bound. It may be read with profit by all students of anesthesia and by teachers who will find much that is worthy of imitation in this course of lectures.

Die Grundlage der Geschwulstlehre. Von Dr. K. A. Heiberg. Paper. Price 4 marks. Pp. 75 with 11 illustrations. Leipzig: Curt Kabitzsch, 1933.

This pamphlet is devoted to the development of the theory that the change in the cell which induces cancer is an alteration in the chromosome number which in turn produces a new race of cells with enhanced growth capacity. The author's measurements of cells in fixed tissues show that in general the nucleus of malignant cells is larger than in normal cells, the nucleoli also, and that the number of chromosomes is increased. He attributes the invasive properties of the cells to their increased growth energy which is in turn due to the increase in cell dimensions, coupled with hyperplastic changes in the connective tissue stroma, which contribute to the isolation of the rapidly growing neoplastic cell and hence invasion and ultimate metastasis. There must also be assumed a susceptibility of the organism as a whole, which plays a part in the cell alterations. Cancer is therefore a problem of cell growth as has for many years been stated by other students of the subject. The author suggests as an important problem the thorough study of the influence of hormones and vitamins in connection with this susceptibility. There is nothing particularly novel in these ideas of Heiberg's, for many of them have been in print for years and certainly there is no evidence that vitamins play the slightest part in the production of cancer, nor is there any sound experimental evidence that the hormones, when produced in either excessive or diminished amounts, play any part in the tumor process. A good bibliography of pertinent reference is appended.

What to Tell the Public About Health. A Collection of Short Articles Aimed to Present in Simple Terms the Facts About the Prevention of Disease and the Promotion of Health. Cloth. Price \$2. Pp. 255 with illustrations. New York: American Public Health Association, 1933.

This is a collection of articles reprinted from the syndicated health bulletin which for the past five or six years has been furnished by the American Public Health Association to health officers either unable to write their own bulletins or so firmly convinced of such inability that the effect is the same. It has the strength and the weaknesses of all syndicated material, namely, that it is accurate, dependable and probably better written than local productions would be while on the other hand it lacks the definite local applicability and interest that attach to a strictly home product. One section deals with newer books about health education and still another contains the names and addresses and a brief statement of services offered by organizations that supply health education material. This list includes commercial organizations, which have been selected, with one or two exceptions, in an acceptable manner. The book is not copyrighted, but permission to use the articles should be requested of the American Public Health Association. This is a book which can be commended to the attention of

public relations and educational committees of county medical societies. The brief character of its articles and the attractive make-up of the book, with many illustrations and cartoons, would seem to recommend it to doctors for their waiting room tables.

Die Blutkrankheiten in der Praxis. Von Professor Dr. P. Morawitz. Klinische Lehrkurse der Münchener medizinischen Wochenschrift. Band I. Second edition. Paper. Price 2.50 marks. Pp. 70. Munich: J. F. Lehmann, 1933.

This treatise consists of ten chapters, covering practical methods of blood examination for the practitioner, diagnosis of pernicious anemia, cause and treatment of pernicious anemia, constitutional hemolytic anemia, pathology and treatment of chlorosis and secondary anemia, the leukemias, lymphogranuloma and other leukemoid diseases, hemorrhagic diathesis, polycythemia and other megalosplenias, and symptomatic changes in the blood. The author urges the use of fresh films for rapid study and the Jenner-May-Grunwald stain with methylene blue as a suitable stain for the study of leukocytes. In pernicious anemia he recommends the use of fresh liver juice as most generally valuable and speaks of the use of six weeks' intensive therapy with arsenic. He strongly recommends splenectomy in chronic hemolytic icterus. True chlorosis is on the increase in Germany, Switzerland and Scandinavia. It affects only females at the age of puberty. The attacks are periodic and especially during winter. Menstrual irregularity in the milder cases and amenorrhea in the severe cases is the rule. Achlorhydric anemia is a disease of women above 20 and responds to large doses of hydrochloric acid and iron. Iron is of no use in the anemias of tuberculosis, cancer, nephritis or sepsis. In one case of acute aplastic anemia the author found improvement by massive transfusion and splenectomy. In the leukemias he warns against the use of benzene and splenectomy. Roentgen therapy may make the condition acute and lead quickly to death. In the hemorrhagic maladies, he mentions three preliminary tests in diagnosis: bleeding time, Rumpel-Leede phenomenon, Koch's test, and the determination of the time of disintegration of blood platelets and also their count. In conclusion he emphasizes the necessity for the study of the chemistry as well as the physicochemical properties of the blood and the influence of outside agencies and the methods of determining various poisons in the blood. The treatise is sound, deals with known facts as far as possible, and has enough of the personal point of view of an experienced clinician to make it of interest to the practitioner.

Prominent Danish Scientists Through the Ages with Facsimiles from Their Works. Edited by V. Nielsen, M.D. University Library of Copenhagen 400th Anniversary. Paper. Pp. 195 with illustrations. Copenhagen: Levin & Munksgaard, 1932.

This is a commemorative volume containing brief sketches by different authorities of forty-five leading Danish men of science of the past, with concrete reviews of their most important achievements. A conspicuous and interesting feature is the facsimile reproduction of a characteristic fragment of the work of each scientist—a page of manuscript, a printed page of text, a title page or a plate. Medicine is well represented, eighteen of the forty-five scientists being listed as physicians. By this book the University Library of Copenhagen pays a worthy and fitting tribute to Danish leaders in scientific work.

Arbeit und Gesundheit. Sozialmedizinische Schriftenreihe aus dem Gebiete des Reichsarbeitsministeriums. Herausgegeben von Professor Dr. Martin Beck, Ministerialdirektor im Reichsarbeitsministerium. Heft 21. Die soziale Bedeutung und Beurteilung der Kreislauferkrankungen. Von Dr. med. Franz Grünbaum, Reg. Med. Rat und Leiter der Versorgungs-Kranstalt Bad Nauheim. Paper. Price 4.50 marks. Pp. 128 with 20 illustrations. Leipzig: Georg Thieme, 1933.

This booklet concerns itself with tuberculosis and heart disease in the field of industrial hygiene and public health. It is especially directed to the day by day physical exaction of work and the increased susceptibility of the worker to occupational diseases and the early causation of degenerative disease because of this day by day immeasurable toll taken by all prolonged physical labor. Throughout are many references to the application of the German workmen's compensation law, and particularly the occupational disease law. The author advocates compulsory physical examination, increased medical care, hospitalization, and baths wherever indicated. Among other headings, the following are cited as reflecting the general

trend of the booklet's contents facts regarding the length of life and general health of the nation, rates of deaths from various diseases, numbers of those involved but still alive cause of these conditions and the rehabilitation of the patient, rheumatism, syphilis and arteriosclerosis as contributing factors and their influence on the "span of life", determining the patient's ability for work the enlarged heart and its relation to bodily function palpitations high blood pressure chronic cardiac weakness as related to ability to work, trauma and the impaired heart the social problem involved bath cures and sanatorium treatment, social interest, financing and obligations involved.

Panamá y su legislación social Por el Doctor José Guillermo Lewis
Cloth Pp 254 Madrid Javier Morato 1932

This book presents the efforts made in Panama in the years 1929 and 1930 to promote the public health and safety of its people. The author has been instrumental in advancing public health conditions in Panama. As a result, some laws safeguarding the public health are now existent. One of the first laws passed was law 23 of 1930 providing for the welfare of the pregnant women employed in the industrial and commercial houses. These women shall not work for a period of eight weeks before and after childbirth. Foundling hospitals for the care of the children have been established and these are under the direction and guidance of the department of national hygiene. There exists a section of industrial hygiene which performs periodic health examinations of the employees of the industries. There are many letters and editorials in this book by prominent individuals of Panama and foreign countries discussing the necessity of public hygienic measures in Panama and praising the noteworthy work done by Dr Lewis for the people of Panama.

Practical Food Inspection By Charles R A Mortin MRSI
A MISE Senior Sanitary Inspector Whitstable In two volumes
Volume I Meat Inspection Cloth Price 15/- Pp 312 with 138
Illustrations London H K Lewis & Company Ltd 1932

This is the first volume of a work on the important postwar technical and administrative development in food inspection in England for inspectors and students written by a practical inspector and comprising data collected during routine inspections over a period of years. The illustrations of pathologic conditions are drawings of actual morbid specimens from slaughterhouses. The matter is condensed for practical use, scientific details superfluous to working needs of inspectors have been omitted, but animal pathology is quite completely treated. The volume includes chapters on physiology and comparative anatomy, age indications sexual differences and antemortem inspection, slaughterhouses and slaughtering dressing of animals and preparation for sale, a system of meat inspection, physiologic abnormalities and malformations, pathologic abnormalities, infectious diseases, chronic diseases, septic diseases, contagious diseases, parasites, and preservation of meat. A glossary of terms is appended. The book is useful for government meat inspectors and health officials.

Morale The Mental Hygiene of Unemployment for Unemployment Relief Workers Social Workers Public Health and Visiting Nurses Community Chest Executives Public Officials Clergymen and Members of Boards of Philanthropic Organizations By George K. Proit MD
Paper Pp 64 New York National Committee for Mental Hygiene, 1933

This booklet is frankly intended for social workers and those who have to do with the unemployed. It is written in a manner which indicates that the writer has more than a theoretical knowledge of psychic and psychologic problems connected with the administration of charitable relief. The book goes into a number of important problems, beginning with a discussion of how mental health is affected and dealing at length with the question of security or insecurity and its influence on people's attitudes. The conditions necessary for good mental health are briefly outlined, emphasizing the importance of work and of "blowing off steam" through such devices as soap box oratory. The effect of depression on family life is considered, including relationships between former wage earners and their former dependents and especially, the adolescent members of the household. The book concludes with suggestions emphasizing that rules cannot be offered. There is a good bibliography. The book has a combined index and table of contents in the front,

and the important paragraphs have conspicuous headings. The make-up is attractive. The price makes it possible for any one to have it, and it should be in the hands of social workers and others who have to do with the unemployed.

Kinderärztliche Technik Zum Gebrauch in Klinik und Praxis Von Dr. Hans Behrendt Kinderarzt am St. Markus Krankenhaus Frankfurt a. M. Boards Price 6 marks Pp 122, with 73 illustrations Leipzig Georg Thieme 1933

This manual contains information designed to acquaint the practicing physician with the special technique and methods used in pediatric practice. Methods for introduction of fluids and foods into the stomach and for obtaining samples of gastric and duodenal contents are given. The rectal drip, enemas, intubation and inhalation methods are described. The technique for pericardial and pleural puncture is given, though the illustrated implements for the latter procedure, pictured on pages 25 and 27, are rather formidable looking weapons. Such procedures and methods as intraperitoneal injection, intrasinus puncture and intravenous injection, and transfusion are discussed and illustrated. The various skin tests are described, and methods for lumbar, cisternal and ventricular puncture are elucidated. The average intern in a good pediatric service will have mastered all the technical procedures described. Several excellent manuals on pediatric procedures and technique, published in English, have been available for the last few years.

Die wichtigsten Vergiftungen Fortschritte in deren Erkennung und Behandlung Von Erich Leschke a. o. Professor für Inneren Medizin an der Universität Berlin Mit einem Anhang Zur Prophylaxe der Vergiftungen. Von Ministerialrat Professor Dr. Franz Koelsch Die Erkennung von Vergiftungen an der Leiche Von Professor Dr. Karl Meixner Klinische Lehrkurse der Münchener medizinischen Wochenschrift Band XI Paper Price 6 marks Pp 308 with 29 illustrations Munich J. F. Lehmann 1933

The author deplors the fact that a knowledge of toxicology is not more generally in the possession of the medical profession. According to Zangger, 80 per cent of cases of poisoning are not recognized. This book differs from most others on toxicology in that it is not written by a pharmacologist but by a clinician and for clinicians. In Germany, barbitol poisoning is most frequently encountered (seventy-seven cases) with morphine next in order (forty-five cases) and compound solution of cresol, adalin hydrochloric acid and phenobarbital (each about ten cases) accounting for two thirds of all cases of poisoning in a certain series and most of these suicidal. The exposition of the subject is so thoroughly modern that it is a book well worth having even in a library that boasts any number of books on toxicology.

Trafikdødsfald i retsmedicinsk Belysning En retsmedicinsk Studie paa Grundlag af 380 legale Obduktioner af Individuer omkomne i Trafikken Af Torben G. Knudtzon [Traffic Mortality from Point of View of Legal Medicine. Medicolegal Study on Basis of 380 autopsies of Individuals Killed in Traffic Accidents.] Paper Pp 351 with 26 illustrations Copenhagen Levin & Munksgaard 1932

This monograph analyzes in detail the results of legal necropsies in the medicolegal institute in Copenhagen in 380 traffic deaths. It is an important contribution to medicolegal literature. There are chapters on the nature of the material studied, on the external and internal lesions produced under various circumstances, on the causes and modes of death in traffic accidents, and on the legal aspects of modern traffic death. It is shown that in certain cases the character of the lesions in the dead body may point to a particular kind of traffic trauma. An important outcome of this work is emphasis on the need of a complete medicolegal necropsy in practically every instance of death connected with street or highway traffic. A necropsy is required if an effort is to be made to answer as fully as possible the many questions that may be presented by such deaths. In Europe, legal necropsies are practiced on an increasing scale in this field.

Behind the Door of Delusion By Inmeta Ward 8 Cloth. Price \$2 Pp 325 New York Macmillan Company 1932

This book was written by a patient in a state hospital for the insane. He went in of his own volition for dipsomania, and this book, having passed through several printings, will probably pay his expenses. It is a revelation of the lives of the inhabitants of such institutions. Dr. Jelliffe considers its author one of the sanest authors of the season. This is not necessarily a compliment. The book is well written.

Carbon Dioxide Mixtures in Psychoses—D'Elseaux and Solomon observed thirty patients in their response to inhalation of carbon dioxide. They studied the responses in one of the patients in detail, and the data obtained form the chief basis for their study. In all the cases the condition was classified as stupor on the basis of a more or less complete lack of contact with the environment as shown by the overt behavior. They describe several different means of arousing patients from stupors and the changes induced by them. The authors conclude that not one of the physiologic changes is essential to the arousal. The change in the mental activity of the patient appears to depend on the nature of the shock to the body economy caused by each procedure used. Certain psychologic factors have been shown to alter the response. It is believed that none of the hypotheses known and advanced in explanation of the phenomena are adequate. The work indicates that the physiologic and mental factors complement each other.

Syphilitic Amyotrophy—Mackay and Hall report four cases representing a form of progressive muscular atrophy due to syphilis. As a group these cases exhibit historical physical and serologic evidences of syphilis, the atrophy often begins with pain, most frequently involves the upper extremities and not uncommonly occurs first in the shoulders and simultaneously or later in the hands, and it may be extremely patchy in its distribution. The pyramidal tracts may or may not be involved. The pathology of the group reveals much confusion but seems to indicate a syphilitic meningo-radiculo-myelitis as the basis for most cases, with the question of a truly parenchymatous and selective syphilitic disease of the anterior horn cells as yet unsettled. The authors believe that vigorous antisyphilitic treatment in syphilitic amyotrophy can do no harm and may in many cases do much good. When a reasonable suspicion exists as to a syphilitic etiology, they are convinced that active treatment should be instituted with a judicious combination of arsphenamine, tryparsamide, preparations of bismuth and mercury, and the administration of artificial fever.

Gliomas in Region of Cauda Equina—Kernohan and his associates base their histologic observations on a study of twenty-five cases of tumor of the spinal cord. The histologic structure of the spinal cord is similar to that of the brain, and in their study of intramedullary tumors they found them to correspond in type with tumors arising from the substance of the brain. Most of the gliomas that occurred in the region of the cauda equina arose either from the conus medullaris or from the intradural filum terminale, although it is possible that some at least could have arisen from glial or ependymal heterotopic masses attached to the nerve fibers of the cauda equina. As in cases of tumors situated elsewhere in the spinal canal, pain was the initial complaint in more than 80 per cent of the cases. The pain suggested a tumor in twelve of the twenty-five cases, it suggested sciatic neuritis in four, and it was atypical for either a tumor or neuritis in eight. The pain was limited entirely to the spinal region in two cases to the sciatic

distribution in two and to the back and to the sciatic distribution on one or both sides in twenty-one cases, and it presented the superficial appearance of bilateral sciatica in sixteen cases. The most diagnostic data were obtained on spinal puncture: the fluid removed was yellow in eighteen cases, and the needle entered the tumor in eight. A spinal puncture should be done as part of the general examination in more cases in which one suspects sciatic neuritis. Fifteen of the eighteen tumors of the filum terminale were completely removed and three were only partially removed. Recovery for periods up to thirteen years without recurrence has been obtained with the removal of the tumor and wide resection of the filum terminale. Only partial and temporary relief was obtained by partial resection, decompression and roentgenotherapy. Complete resection of the tumors was done in one case and partial resections in six cases in which the lesion involved the conus medullaris and the filum terminale. Two of these patients recovered to the extent that they were able to carry on their regular vocations for three years. The remaining patients did not improve appreciably. The resection of the conus medullaris containing the tumor is justifiable if there is a fair prospect of including all visible growth.

Degeneration of Spinal Cord—Winkelman and Davison state that in a study of twenty-five cases diagnosed as pernicious anemia with changes in the spinal cord, twenty presented nothing unusual in the histologic pictures. These showed the typical funicular myelopathy that is characteristic of this disease. In five cases there was, in addition, a perivascular round cell infiltration, mainly in the posterior and lateral portions of the spinal cord. Differential staining methods were used in an effort to determine whether the condition was inflammatory or degenerative. The majority of the perivascular cells proved to be of the compound granular cell type in the cases of pernicious anemia. In contrast to this, dementia paralytica was studied by the same methods, and the plasma cell and lymphocyte were found to be the predominating round cells. The term 'small round cell infiltration' is therefore a noncommittal description of cells lying in the perivascular spaces. While it is true that degeneration is part and parcel of an inflammatory process, inflammation is not usually part of a degenerative condition. The authors think it is worth while to make a distinction between inflammation and degeneration, only by this distinction will it be possible to arrive at a knowledge of the basic type of change that is going on.

Arkansas Medical Society Journal, Little Rock

29 181 204 (Feb.) 1933

*Indications for Surgery in Pulmonary Tuberculosis F H Krock, Fort Smith—p 181

Economical Side of Medical Practice. J S Wilson, Monticello—p 188

*Kline Test for Syphilis F M Smith Hot Springs—p 192

Surgery in Pulmonary Tuberculosis—Krock believes that the surgical treatment of pulmonary tuberculosis is able to save about 40 per cent of the patients with far advanced tuberculosis in whom it is indicated. The indications for phrenicectomy are (1) in predominantly proliferative tuberculosis with cavitation, especially as a preliminary procedure to thoracoplasty, (2) as an independent procedure in the proliferative type with cavities in the lower or middle lobes, (3) in circumscribed disease of the upper lobe, (4) in the severe and moderately severe progressive febrile predominantly exudative type of phthisis when no result has been obtained by pneumothorax, and in which light or moderately severe involvement of the opposite lung may be present, (5) in the unilateral fibrotic type with tachycardia due to displacement of the heart, (6) to relieve persistent hemoptyses when pneumothorax is unsuccessful, (7) in the treatment of recurrent fluid, especially tuberculous empyema, and (8) in those cases of satisfactory collapse after artificial pneumothorax when refills at the necessary intervals cannot be obtained by the patient. The chief indications for thoracoplasty are (1) severe unilateral tuberculosis with cavities which has not responded to other measures of treatment, (2) moderately severe proliferative tuberculosis with marked deviation of mediastinum and interference with the heart action, (3) unilateral, chiefly exudative, type of infection which is progressive in spite of pneumothorax treatment, (4) empyema following pneumothorax, with or

without drainage, (5) repeated severe hemoptyses not controlled otherwise, and (6) treatment of spontaneous pneumothorax of the valvular type.

Kline Test for Syphilis—Smith made a comparative study between the Kline test and the Kahn and the Kolmer modification of the Wassermann reaction on 3,600 blood specimens. These serums were inactivated at 37 C for thirty minutes. The Kolmer and Kahn tests were run according to their respective techniques. The Kline emulsion was made up according to the formula given in the October 1932 issue of the *Journal of Laboratory and Clinical Medicine*. Of the 3,600 specimens tested, 2,039 were negative and 962 were positive in all three tests, thus giving a complete agreement on 30,001 tests, or 83.69 per cent. The Wassermann and Kline reactions agreed in 87.09 per cent, the Kahn and Kline in 84.69 per cent, and the Wassermann and Kahn in 90.21 per cent. Of the serums tested, 599 or 16.31 per cent, failed to agree in one or more of the three reactions. These serums were classified as proved syphilitic, treated or untreated, doubtful syphilitic, treated or untreated, and nonsyphilitic. The author concludes that his work proves the Kline test to be an accurate serologic test for syphilis, having certain distinct advantages over the Kahn, Kolmer and Wassermann, in that the simplicity of the Kline technique and stability of the antigen decreases the source of error and makes it a desirable laboratory procedure.

Surgery in Pulmonary Tuberculosis. R. B. Bettman. Chicago.—p. 181.

Treatment of Chorea Minor—Whitaker discusses the two outstanding therapeutic procedures in vogue today for the treatment of chorea minor: phenylethylhydantoin and the production of fever by paratyphoid vaccine. In properly controlled cases without evidences of existing complications there seems to be no danger from the use of phenylethylhydantoin in the treatment of chorea minor in childhood. Suggestive evidence is appearing that phenylethylhydantoin may be of definite antirheumatic value. Certainly, its effects in shortening the duration of chorea is not solely the effect of the induction of fever. By the use of phenylethylhydantoin and the shortening of the active stage of chorea the incidence of subsequent carditis may be lessened. Phenylethylhydantoin offers a valuable aid in therapy particularly in the more severe cases of chorea, although there is no definite reason why it may not be used in even the mildest cases.

Xanthomatosis—Dahltsch states that a review of the previously reported cases of Schüller-Christian's disease indicates that dental and oral lesions and jaw bone involvements are frequent and usually early manifestations. They often are the initial complaint and often precede other symptoms by a considerable length of time. The author reports a case of xanthomatosis with the characteristic features of oral lesions, bone defects, diabetes insipidus and proptosis, and having the peculiarities of early marked bone defects in the mandible occurring two years before defects occurred in other bones and an onset at the age of 29. He places emphasis on the advisability of

a thorough study of jaw lesions as a means of identification and early recognition. Schüller-Christian's disease should be considered in cases of stomatitis, loosening of the teeth and bone rarefaction of unusual character, and, on the other hand, oral lesions should be looked for in cases showing diabetes insipidus, proptosis and other bone defects, especially those of the skull. Constant pain is also a symptom of the bone disturbance.

Surgery in Pulmonary Tuberculosis—Bettman points out that, in pulmonary tuberculosis, thoracoplasty must not of necessity be reserved until medical treatment has failed. Thoracoplasty must not be considered apart from the general sanatorium treatment of tuberculosis. It should be recognized as much a part of a routine treatment in certain instances as artificial pneumothorax, graded exercises, or any other of numerous procedures. The conventional extrapleural thoracoplasty is by no means the only method of treatment. Selective collapse will undoubtedly take an important place in the surgery of tuberculosis. The author believes that the importance of phrenicectomy has been greatly overestimated. There is no such division in the treatment of tuberculosis as medical or surgical treatment. It only happens that at some stages during the treatment the phthisiotherapist is the more active of the medical attendants, at other times the surgeon.

Carcinoma of Esophagus—Eggers presents seventeen cases of carcinoma of the esophagus, five of which affected the upper end, nine the thoracic portion, and three the cardia. Not one of these was an early case. In the majority, symptoms had existed for more than six months before a correct diagnosis was made. In several patients in whom the diagnosis of cancer was suspected, too much importance was attached to a negative roentgen examination. In all patients in whom symptoms persist reexamination is urgently indicated. Esophagoscopy with biopsy is the surest way to make a diagnosis. A

negative report should not be accepted as final if the symptoms are suggestive. Unfortunately, there are no real early symptoms. It is usually not until there are symptoms of difficulty in swallowing that the patient complains. All these patients should be examined with every means at one's disposal, especially roentgenography and esophagoscopy. Not until patients are referred for surgical treatment before they have become emaciated, dehydrated and discouraged and with the local disease far advanced will it be possible to achieve substantially better results. An operation for carcinoma of the esophagus will always be a formidable one, even with an early diagnosis and the patient in a fair condition. However, the technical difficulties have been largely mastered, so that the problem looks less difficult than it did some years ago. It was possible to remove the tumor and complete the operation in only thirteen of the author's seventeen cases. Of this group four patients recovered and lived for months; a recovery of almost 32 per cent. There were two recoveries among the five upper esophagus cases, a mortality of 60 per cent, and two recoveries among the five patients in whom a carcinoma of the thoracic portion was resected, likewise a mortality of 60 per cent.

Intrapleural Pneumolysis in Treatment of Pulmonary Tuberculosis—Gorsee believes that his critical analysis of twenty-eight cases of pulmonary tuberculosis in which thoracoscopic examination and cauterization of suitable adhesions was carried out warrants the following conclusions: 1. Closed intrapleural pneumolysis is often a necessary adjunct to the artificial pneumothorax treatment of pulmonary tuberculosis. 2. Of the twenty-six cases treated by cauterization of pleural adhesion by closed intrapleural pneumolysis 61.5 per cent were favorably influenced in their clinical course. 3. Postoperative complications vary almost directly with the clinical condition of the patient and the type of adhesions cauterized. 4. The electrosurgical method of closed intrapleural pneumolysis decreased the number and severity of operative and postoperative complications by adequate coagulation of the adhesions prior to their severance and by lessening the amount of heat and smoke liberated during cauterization. It is therefore superior to the galvanocautery technic for cutting pleural adhesions.

*Common Vesicular Eruptions of Hands and Feet C O West Kansas City—p 43

Surgery in Treatment of Pulmonary Tuberculosis E C Padgett Kansas City Mo—p 47

*Gastro-Intestinal Allergy Consideration of General and Clinical Features H J Rinkel Kansas City Mo—p 53

Vesicular Eruptions of Hands and Feet—West states that the lesions of dyshidrosis and pompholyx contain fungi, and that they usually appear in the warm months on the non-hairy areas, especially the lateral aspects of the fingers or the palms of the hands and soles of the feet. These lesions are, as a rule, symmetrical and are filled with a clear fluid of a water-like viscosity. The disease occurs in the second and third decades of life. In industrial dermatoses the main irritants are plants, animals or minerals. These lesions present at times a typical series of vesicles, the most common location being the hands. It is important to delve into the patient's occupation. In anaphylactic dermatosis the lesions are usually bilateral and have nearly always a period of vesiculation with periods of regression. The exciting cause is often ingested foods or drugs. The author has observed a vesicular eruption of sudden onset which at first presents a clinical picture of mycotic infection and does not respond to salicylic pastes. The walls of these vesicles are of medium thickness filled with fluid of light viscosity, rupturing rather easily, with a tendency to coalesce. The lesions are quite generalized and negative for fungi and yeast. The sympathetic nervous system evidently plays a part in this type of lesion. The mycotic infections of the hands and feet are intertriginous vesicular and hyperkeratotic. The fungi of the vesicular type can grow indefinitely on bathroom floors, gymnasium floors, locker rooms, club rooms, swimming pools, handles of tools, automobile steering wheels, golf club handles, tennis rackets, baseball gloves or shoes. According to White, 25 per cent of the ringworm eruption on the hands and feet is vesicular. The ringworm vesicles

are deep seated, hard, shotty, with bluish steel colored centers and a lighter periphery, containing a heavy, sticky viscid fluid, multiform in size, showing varying ages of the vesicles and a more progressive development—a differentiation from other vesicular lesions that give rise to lesions of about the same size. Ringworm has a predilection for the sides and lower tips of the toes and the arch of the foot, leaving the heel and ball free of lesions. In dermatophytid the onset is sudden following an old long-standing tinea of the toes. The essential feature of the sudden attack may be a sensitization of the skin changing its resistance to the mycotic infection or the toxins it produces. Vesicular lesions of nervous origin may be treated with roentgen rays, a bland ointment or wet packs and some sedative. In industrial dermatosis the avoidance of the exciting cause and the free use of water is beneficial. The early application of a bland ointment such as ointment of rose water and hydrous wool fat or a wet pack is advisable. Pompholyx and toxic eruptions respond to a mild symptomatic individualized treatment of equal parts of tannic and boric acid, 1 drachm to a pint of water used as a wet pack. A dilute potassium permanganate or aluminum acetate and boric acid pack is also helpful. There is no panacea for the treatment of fungous infection. The roentgen ray is the most useful combatant yet found to attack fungous infection, particularly when assisted by Whitfield's ointment full strength, or modified either in strength or by the addition of essential oils. Mercurochrome is of little value as a fungicide. The use of salicylic acid mixtures as a panacea in vesicular lesions should be guarded.

Gastro-Intestinal Allergy—According to Rinkel, gastro-intestinal allergy includes only the primary lesions induced by the allergic reaction. These changes predispose to secondary pathologic lesions of great importance. The exciting reaction may be inside or outside the enteric tract and may be induced by one or several forms of hypersensitiveness, atopy being the most common. Digestive tract symptoms due to allergy mimic other gastro-intestinal diseases and are rarely present as a distinct clinical entity. Lesions may occur at any level of the tract. They may be induced by a single ingestion or by the cumulative or combined effect of a food or foods. Food is the commonest cause of enteric tract allergy and is more frequent in children than in the adult. A gastro-intestinal study should incorporate details concerning the family and past history of allergy as well as an evaluation of signs indicative of sensitization in the patient. Interpretation of food distress is to be made with care since there are many types. The differentiation of acute abdominal conditions is to be made with caution; the error being toward an infectious lesion with surgery rather than that of allergy and delay. Skin testing is to be done along with other laboratory procedures, never alone. In every instance, clinical trial is the means of specific diagnosis. The direct or differential diagnosis is not difficult if one will consider the probability of allergy in atypical acute and every chronic abdominal condition. Treatment should be aided by general medicinal and hygienic measures. The inability to maintain health and avoid exciting foods may complicate treatment.

*Primary Jugular Bulb Thrombosis with Metastasis Operation Recovery S Mahis Los Angeles—p 132

New Tonsil Knife and Enucleator S P Schechter New York—p 138

Primary Jugular Bulb Thrombosis—Mahis concludes, from a study of a case of primary jugular bulb thrombosis, that 1. The great problem in sinus thrombosis is not so much the etiology or the operative technic but the early recognition of the infection of the sinus, as the danger increases with each day. 2. A metastatic phenomenon with sepsis may act as an aid in the diagnosis and at the same time be mis-

leading, for the patient may have a hematogenous septic arthritis from a middle ear infection which would account for septic temperature, chills and positive blood culture, without sinus involvement. 3 The time element and the patient's condition at the time of the operation are important factors in guiding one as to what and how much to do. 4 Arthritic metastases following otogenous general sepsis are not immediately to be feared and are least dangerous from a prognostic point of view. McDaniel reported a case of jugular bulb thrombosis complicated by several arthritic purulent infections with complete recovery following incision and drainage of more than 500 cc. of pus from the right thigh.

Effect of Relaxants During Labor.—Dodek calls attention to an original method and apparatus previously presented for external hysterography during labor. References have been made to the experimental work of other observers with the action of epinephrine solutions on the uterus of the human female and of laboratory animals. External hysterograms reveal that solutions of epinephrine in 1:1,000 dilution and in doses of from 3 to 15 minims (0.2 to 1 cc.) inhibit completely the contractions of the human uterus in labor for periods varying from four to sixteen minutes. The inhibitory effect of epinephrine on the contractions of the parturient human uterus is of value in obstetric practice, to relax a contraction ring or a tonic uterus with the help of general anesthesia when these conditions interfere with safe operative termination of the second stage of labor vaginally. The rapid antagonistic action of epinephrine to pituitary extracts should be kept in mind in cases of the inadvised use of the latter during first or second stage labor. Despite the analogous properties of ephedrine and epinephrine, the former does not have an inhibitory action on the contractions of the human uterus in situ.

Infection in Burns.—Aldrich observed, through bacteriologic studies on a series of burned patients that the beta-hemolytic or gamma streptococcus was the invading organism

in all extensive burns. When a surface of the body is burned there are no marked constitutional changes if the burns are kept free of infection. Gentian violet is highly bactericidal against the gram-positive organisms. Gentian violet is a coagulant and an analgesic agent in burns; there is no loss of fluid from the burned area which is sealed under the eschar. Invasion by contaminating organisms is kept down to a minimum. The patient is practically free from pain. In third degree burns there are many small islands of epithelium in the hair follicles that will spread under the scaffolding of the eschar when infection is kept down, hence diminishing the necessity for skin grafting. The author reports a few typical cases. One patient presenting a third degree burn of three fifths of the body area lived eighty-four days and showed at necropsy none of the changes that are supposed to be associated with burns. In the treatment of burns with gentian violet when a patient is admitted with a fresh burn unless it is covered with oils or grease there is no need to do any preliminary cleaning, the dye in a 1 per cent solution being sprayed on the burned area immediately. The usual procedures to combat any existing shock are carried out. The patient is so placed that the burned area is uppermost. The burn is not covered with a dressing. The bedclothes are supported by a cradle in which a light bulb is placed to keep the patient warm. The temperature under the cradle is maintained between 84 and 88 F, this being the temperature found to be most comfortable for the patient. For the first few hours gentian violet is sprayed on the burned areas every two hours. A light eschar is formed rapidly; the wet oozing areas becoming dry and tough. The burn is thereby sealed sterily under an impermeable cover. By the time the preliminary sedative has worn off pain has ceased. After the eschar has formed the patient is sprayed every four to six hours during the day. Any blebs that have formed are opened and the unstained portions are sprayed. This treatment continues until healing is complete. If the burn is so deep and so extensive that skin grafting is going to be necessary, the eschar is allowed to remain on for about three weeks, after which time it can be softened and removed by warm compresses of sterile salt solution. By that time the granulations have built up enough to graft and being sterile, they accept new skin readily. If a patient presents himself with an old burn already septic, the treatment can also be instigated with no initial clean up. The necrotic matter and pus are likewise converted into an eschar, but this eschar differs from that of a fresh burn by being irregular in pieces and floating. This eschar is usually removed every day and the area sprayed immediately afterward. Otherwise the treatment is the same as that described for fresh burns. The general care of the patient is of prime importance. This includes forcing of fluids and a high vitamin and high caloric diet.

Lead Treatment of Cancer.—Aub and Smithwick report the results of treatment of twelve cases of cancer of the breast by a combination of intravenous injections of lead orthophosphate followed by high voltage roentgen therapy. Intravenous lead treatment as given to these patients did not seem to exert any depressor effect on the rate of growth of tumor cells. The addition of varying degrees of lead poisoning with the accompanying secondary anemia to the already existing disease probably made the duration of life of these patients shorter than it would have been with roentgen treatment alone. It was difficult to control adequately the symptoms of lead poisoning by diet and calcium chloride alone. Morphine was frequently necessary to relieve the intense pain of lead colic. In spite of metastases to the bones, the calcium excretion of four of these patients averaged only slightly higher than that found in normal control subjects. This calcium excretion was not influenced either by roentgen treatment or by the injections of large amounts of lead. The lead that was injected averaged 473 mg. in six of the patients. An average of only 69 mg. of lead was recovered in the excreta in the next forty-six days, so that approximately 400 mg. was retained in the body.

Antirachitic Potency of Milk of Mothers Fed Vitamin D Milk.—According to Bunker and his associates, breast milk from mothers who have not previously been fed antirachitic supplements to a mixed diet does not heal rickets in rats when each animal is fed 20 cc. of milk daily for eight days. Breast milk from mothers who daily received 24 ounces of vitamin D milk for two weeks as an antirachitic supplement to an other-

wise adequate diet is found to contain antirachitic potency equivalent to 1 rat unit in 136 cc of breast milk (17 cc. daily per rat for eight days). Two out of eight animals showed little or no healing. Thus breast milk when fed at the rate of 15 cc daily per rat for eight days (120 cc total) shows definite increase of antirachitic potency over breast milk that has not been built up by a supplement of vitamin D milk. When fed at the rate of 20 cc daily per rat for eight days, the 160 cc. total fed per animal shows well over the equivalent of 1 rat unit. The antirachitic potency of human breast milk can be augmented in a simple and acceptable manner by including vitamin D milk in the diet of the mother, during lactation.

Positive Blood Reactions in Treated Syphilis—Wheeler studied 200 patients with persistently positive serum reactions. Only 8 of the 200 patients presented neither lesions nor symptoms. A large majority (147) of the patients started treatment from two to forty years after the date of infection. Seventy patients had irregular or insufficient treatment particularly lacking in arsenicals, these patients demonstrated that untreated or insufficiently treated syphilis is a serious menace causing grave damage to the nervous, vascular and visceral systems. Although modern treatment is not finally ideal and has certain disadvantages, it is nevertheless of essential value until further progress is made. It is reasonable to suppose from the observations made in this study that organic syphilitic involvement is in most instances the cause of persistently positive serum reactions, and that such reactions usually mean uncured syphilis.

Diathermy in Treatment of Chronic Deafness—Yazujian treated four patients suffering from advanced catarrhal deafness and one from moderate nerve deafness, perhaps a sequel of erysipelas. All obtained satisfactory hearing from this treatment. He has also used diathermy in ordinary chronic conditions, combining it with the routine treatment and believes that it expedites the recovery of hearing. The patient should be seated in a comfortable chair and assured that there will be no pain, shock or any discomfort during the treatment. An 8 per cent solution of cocaine should be applied once to the nasal mucous membrane as far as the posterior choana. While the cocaine is taking effect, cotton should be wound on the triangular ends of the nose and ear electrodes so as to form a cylinder, and care should be taken that the points of the electrodes are well covered to a thickness of about 25 per cent more than their insulation. The cotton-covered electrode tips are then dipped in physiologic solution of sodium chloride, the excess fluid being gently squeezed out. The ear electrodes are placed in their holders and the operator, stretching apart the two ends of the head band which holds the ear pieces, introduces a tip into each meatus and brings the holders in alignment with the meatal passages horizontally. The latter are then gently pushed in toward the drums two thirds of the depth of the canals, but under no circumstances allowed to touch the drums. Next, the nasal electrodes are introduced in contact with the floor of the nose and until the posterior pharyngeal wall is reached. Over the outside ends of the aural and nasal electrodes are slipped the tubal ends of their respective cords. The dials on the current reducer are set at maximum and then one of the gaps of the diathermy machine is opened slowly until the spark is just visible. In a few seconds the patient will begin to feel heat in the ears. It should be explained that gentle heat is desired and that, if the heat becomes intense, he must immediately tell the operator. If one ear feels too hot, the reducer on that side should be retarded, if both ears get too hot, the gap should be narrowed. While the current required is from 30 to 60 milliamperes, meters should not be depended on because only a few are sen-

sitive enough to record such a small current correctly. The treatment lasts from fifteen to twenty minutes with the patient feeling comfortably warm in the ears. Immediately following diathermy treatment, pneumatic massage may be given.

Jaundice in Infancy—From a review of the literature, Stewart concludes that icterus neonatorum develops in about one third of all new-born infants on the second to the fifth day of life, and persists seldom longer than ten days. If it is present at birth appears after the first week, or persists beyond the second week, other causes must be considered. Of these, infection is the most important. Fever, although not always present, jaundice of deepening intensity, indications of infection at the umbilicus, and the toxic appearance of the infant may be additional points of evidence for infection. Jaundice as a symptom of sepsis has been too frequently overlooked. A history of the death of jaundiced siblings soon after birth leads one to suspect familial jaundice of the new-born now known as erythroblastosis. The jaundice of congenital hemolytic icterus is never intense and may appear at or shortly after birth. There is a hereditary history and an increased fragility of the erythrocytes. An obstructive jaundice, with urine which stains the diapers and stools of the clay colored variety, indicates either congenital obstruction of the bile ducts or catarrhal jaundice. The latter is accompanied by fever and vomiting and will clear up within one or two weeks, the former is progressive. In cirrhosis of the liver, jaundice develops during the later stages of the process and is accompanied by the usual symptoms. Biliary calculi in children are extremely rare. Syphilis, although usually mentioned, is seldom the cause of jaundice.

Induction of Labor—Mathieu used, in a series of 406 cases in private practice, the castor oil and pituitary extract method of induction of labor. It was successful in 96.8 per cent of the cases. Induction caused no increase in the maternal or fetal mortality or morbidity. Induction was most successful when the head was engaged and the cervix effaced. In the last 206 inductions quinine was not used, and the results were apparently not affected by its omission. In his series of 406 cases there appeared to be no basis for the fear some hold that the use of pituitary extract in the induction of labor causes separation of the placenta. In this number of cases which on close analysis seem to include most of those that promise trouble (the toxemias, eclampsias, large babies, contracted pelvic outlets), the maternal morbidity and the fetal mortality were surprisingly low, in fact, it appears to the author that in his series the induction saved much maternal morbidity and several fetal lives.

Occupational Skin Diseases—Zwick states that as occupational skin diseases have always been present and as the incidence of industrial skin diseases continues high, despite the introduction of labor saving machines which reduce the frequency of contact with harmful substances additional prophylactic measures seem necessary besides those suggested by McConnell, White, and others which retain their usefulness. A cutaneous tolerance test may be useful to detect eczematogenic substances and to detect an eczematous predisposition (sensitivity, idiosyncrasy) in applicants for work. The cutaneous tolerance test is suggested as an additional measure for determining the fitness of an individual for a specific job, besides the customary routine physical examination of the body in general and of the skin in particular. Since 5 per cent of all persons are known to have a congenital defect (idiosyncrasy) of the skin which predisposes to eczema, and since a larger percentage of individuals, on account of their acquired state of allergy (hypersensitivity) have a tendency to eczema, it is the author's idea that the fitness of the largest organ of the body should be investigated more frequently.

Meningococcal Meningitis—Slesinger observed a series of forty-two cases of meningococcal meningitis for periods of from six months to four and a half years following the acute illness. Of these cases, 64.4 per cent showed no postmeningococcal sequelae at the end of the period of observation, and 35.6 per cent showed residual sequelae. The most common complications were hydrocephalus and deafness. The most common residual sequelae were deafness and speech defects. In general, postmeningitic patients showed good physical and mental development. The prognosis of meningococcal meningitis depends considerably on the type of organism that predominates during a given epidemic.

Use of Radium in Brain—In trying to determine the value of radium in the treatment of intracranial tumors, Davis and Cutler experimented on ten cats, nine dogs and one monkey. They used platinum iridium needles with walls 0.5 mm thick, 22 mm long, which contained 1 mg of radium element, for implantation. The pathologic changes consisted of a central zone of destruction immediately in the tract of the needle wound. In the brains of those animals killed at the end of the period of exposure, gutter cells loaded with fat, thickening of the blood vessel endothelium with thrombosis of smaller vessels, amyelinization, and slight chromatolytic changes in the nerve cells were the prominent features. In the brains of those animals in which some reparative processes had time to occur the gutter cells had disappeared, astrocytes and oligodendroglia cells were present in large numbers, and neuronophagia was found. The important fact to be recognized is that these pathologic changes gradually faded away to the normal within the radius of a centimeter from the central zone of destruction. The authors' clinical experience in the use of radium needles implanted within the brain is limited to one case. They first tried to determine whether or not the use of radium element implanted in the brain would produce damage to the surrounding normal brain structure. They used multiple weak radium foci adequately filtered and uniformly distributed. The radium element was distributed throughout the platinum needles in such amounts that the total dose determined by clinical experience is delivered over a prolonged period of approximately five to seven days. When it appeared that irreparable damage did not occur, the authors felt justified in using it in an intracranial glioma. They believe that the case they report was a severe test of the practicability of its use and that its future employment in these extensive gliomas should not be discouraged by the fatal result in this patient.

Treatment of Empyema—Danna discusses the three methods of treatment of empyema that are now in vogue. (1) incision and open drainage with or without rib resection and with or without irrigation of the cavity, (2) closed tube drainage and (3) aspiration. He also discusses a method of periodic aspiration or evacuation of the pus, with air replacement and without drainage. This method removes the pus and produces the same condition that results after tube or any other drainage, that is, a clean cavity filled with air. The cavity is sealed, there is no strain on its walls and the more air present the longer it takes for absorption and the more time the endothelial surface has to return to normal. It is not necessary, therefore, to presuppose that there should be any deviation from the normal process of healing in order to bring about a cure by this method. The advantages of periodic evacuation and air replacement are that it can be used as a preliminary to any other method without harm. It can be used when other methods have failed. It leaves no scar or deformity, especially if a small stab is done before introducing a large needle. The patient is not constantly bathed in pus, is not encumbered with apparatus, and is up and about most of the time. There is less danger of metastatic abscess. The cost of many dressings is saved. There is the least probability of chronic empyema, least

trauma and the greatest probability of minimum residual pleural adhesions. With proper precaution it should be safer and result in a lower mortality than any other method. It is especially valuable in the presence of pulmonary tuberculosis. It lends itself admirably to rendering safer all operative procedures within or through the pleural cavity. The disadvantages of the method are that it should not be used in sudden overwhelming infection of the pleura by ruptured abscess. There is the danger of tension pneumothorax. Chest wall infection is possible. During the intervals between treatments, a certain amount of pus is present giving fever, malaise and so on. This is usually evident only one or two days before the next treatment. It requires a more frequent contact of the surgeon with the patient and more frequent reexamination and roentgenograms.

Cancer of Cervix.—Graves cites Schiller's conclusions that cancer of the cervix starts in the squamous epithelium of the portio near the os and at first spreads laterally, i. e., superficially, it always starts in the unbroken epithelium and not in an ulceration, and histologically the chief determining points of diagnosis are first the oblique line of demarcation between the normal and abnormal areas and, second, the anaplastic atypia and polymorphism of the abnormal cells. In order to discover the location of a process not distinguishable by eye or touch Schiller devised an ingenious test which bids fair to be of general clinical value. The test is based on the discovery by Lahm that the upper layers of the normal epithelium of the portio and vagina contain rich masses of glycogen, which disappear when the epithelium becomes cornified or changed by cancer. In the normal living tissue the glycogen of the upper layers of cells is stained in a few seconds a deep mahogany brown by compound solution of iodine. A superficial area of early cancer being devoid of glycogen does not take the stain and stands out startlingly white or pink against the deeply colored almost black background of the normal tissue. The test is specific for determining the absence of cancer of the portio and vagina. The several conditions that obscure the test are that the stain does not take on glandular epithelium like that of the endocervix, ulcerations and erosions do not take the stain, since they have no epithelial covering; in areas of chronic cervicitis the epithelium seems often to be deficient in glycogen taking a light brown stain which blends with the surrounding deeply staining tissue instead of being sharply defined from it as in cases of true cancer, the normal stain is prevented or obscured by slight trauma such as that from tenacula or scrubbing with gauze; the cervix and vagina of the hypoplastic and atrophic individual stains lighter than the normal, pus stains black, since leukocytes are rich in glycogen, hyperkeratosis prevents the stain as in leukoplakia, syphilis and exposed areas in prolapse the test is of limited value in diagnosing advanced cancer, since the superficial assimilation stage is usually lost in the melee of self-reproducing cells, and Schiller's test is specific for cervical cancer and is not adapted to other superficial cancers such as those of the vulva and skin in other parts of the body. The author's technic is as follows: A thick swab of absorbent cotton and gauze is prepared on the end of a stout wooden applicator. The swab is immersed in the compound solution of iodine until a copious amount of it has been absorbed. With the upper vagina well exposed by speculum or retractors, the swab is then pressed firmly against the anterior lip of the cervix. The upper vagina is in this way flooded with the solution, which instantaneously stains the normal tissues (excepting the mucous membrane of the endocervix) almost black. Any area of the portio, no matter how small, that does not take the stain must be regarded as suggestive of cancer. The suggestive area is then curetted with a specially sharpened spoon curet. The strip of epidermis thus secured is placed immediately in hardening solution and sent to the laboratory for biopsy.

Diverticulosis and Diverticulitis.—David states that the large intestine is probably more frequently the seat of diverticula than is any other structure in the body. The two principal etiologic factors seem to be age and constipation. Adiposity has been mentioned as a predisposing factor but diverticulosis of the colon has been observed in many thin patients. The author has studied histologically a number of sigmoid colons containing small diverticula without inflammation, as well as the colons of aged subjects in whom no clinical

suggestion of diverticulosis existed. He observed at necropsy that the normal sacculations of the sigmoid colon of old people are markedly developed and that small round balls of fecal material can often be expressed from them. The sections of such intestine taken between the tinea opposite the mesenteric border frequently show microscopic diverticula, which do not follow the vessels through the muscularis and consist of herniations of the mucosa and submucosal muscularis and fibrous tissue through the circular muscle. These diverticula show no evidence of inflammatory reaction about them and from the outside of the intestine their presence could not be suspected except in a few instances in which small fecaliths may be seen as dark spots in the subserosal fat. It appears then that, in the aged conditions exist in the muscularis which allow an easy herniation of the mucosa and submucosa. This hernia goes between circular bundles and is at first surrounded by them. After it has completely penetrated the muscularis, the periphery of the sac is covered by mucosa and submucosa consisting of the muscularis, mucosa and fibrous tissue, and over this the subserous fat. As the diverticulum increases in size it commonly insinuates itself into the base of an appendix epiploica, where the body of the sac enlarges into a globular structure and commonly contains dry fecal material or a real fecal concretion. The neck of the sac is small as it penetrates the muscularis, and the opening into the intestine may be difficult to see. During this whole stage of development no evidence of inflammation may be present on histologic study though it is logical to assume that ideal situations exist for inflammation in the body of the sac, which has a narrow opening into the intestine and may be easily occluded.

Urine Test for Pregnancy.—Litterer believes that a reliable and practical test for the determination of early pregnancy is offered by Friedman's modification of the Aschheim-Zondek technic. The time factor has been cut to a twenty-four or a forty-eight hour period, with an error variously estimated between 1 and 3 per cent in the author's series of 200 cases the incidence of error was 2 per cent. Only one rabbit is required in the test. This test finds its real application and value in normal pregnancies. It is subject to an error of from 20 to 50 per cent in abnormal pregnancies. The greatest factor which must be reckoned with in the test is the selection of a rabbit that is more than 8 months of age, weighs at least 6½ pounds (3 Kg.), is unmated, and has been isolated for a period of three weeks or more. Any departure from this rule will invariably lead to disappointing results. Friedman's test when care is taken in the selection of an animal meeting all requirements, is destined to replace other more complicated methods and become established as the test of choice. This test combines simplicity of technic, ease of interpretation of results, low percentages of error and rapidity of performance. The test is as follows: The urine is filtered and preserved with tricresol, then iced. Intravenous injections of this urine are given in the marginal vein of the rabbit's ear. Three injections of from 4 to 5 cc. each are made at intervals of four hours on two consecutive days. Each dose is warmed before injection, as this reduces the possibility of shock to the animal. Forty-eight hours from the time the first injection is given, the rabbit is anesthetized and opened for inspection of the ovaries. A positive test is unmistakable, showing one or more large bulging, shiny, freshly formed corpora hemorrhagica on the surface of one or both ovaries. A negative test consists of several flattened, pinkish or clear cysts appearing partly shrunken and small.

Pink Disease.—Braithwaite states that pink disease is due to an abnormal reaction to daylight in an infected child. It is cured by keeping the child protected from daylight. The cardinal symptoms of the disease are erythredema, a polymorphic rash followed by desquamation, marked anorexia, muscular hypotonia, mental depression, photophobia and sweating. The disease occurs in children following or during an acute infection. It occurs chiefly among well cared for children in good surroundings. Twenty of the twenty-seven cases came from country or suburban homes. It was first described in Australia and has been reported from New Zealand, America and Switzerland. Only four of the present series of cases were admitted during the winter months. The blood calcium is usually raised. Erythrocytosis as well as leukocytosis is extremely common in this disease. There is also often an increase in the amount of hemoglobin. The sedimentation rate may be greatly increased. Intravenous or intraperitoneal injection of sodium citrate usually causes a marked temporary improvement. Keeping the children in light from which the rays of the violet end of the spectrum have been filtered by means of ruby glass causes a rapid and lasting improvement in the condition. In one case exposure to sunlight produced symptoms of collapse.

Treatment of Pyuria.—Rennie treated six cases of chronic pyogenic infection of the urinary tract with the ketogenic diet. At the end of the treatment four patients presented sterile urine, and growth on culture was scanty in a fifth but three relapsed within three weeks. The sixth patient showed no change. In the two patients who were permanently cured the duration of the disease was short and no abnormality of the urinary tract was observed. In each of the four in whom treatment failed abnormality of the urinary tract was demonstrated by pyelography. It would appear that the ketogenic diet is of little value as a curative agent in pyuria associated with abnormality of the urinary tract.

Hemolytic Streptococcus in Acute Rheumatism.—Gibson and his associates ascertained the intradermal reactions to extract preparations of streptococci of different types. Strongly positive reactions to extract of hemolytic streptococcus are more common in rheumatic than in control cases. Reactions to viridans and gamma streptococcus extracts show no significant difference as between rheumatic and control series. There is, however, some evidence that the incidence of reactions to extracts of nonhemolytic streptococci is associated with the degree of sensitivity to antigens of hemolytic strains. The Dick reaction was positive in 16 per cent of the authors' 140 rheumatic cases as compared with 28 per cent of 145 controls. Hemolytic streptococci were isolated from the throats in 43 per cent of the rheumatic cases as compared with 20 per cent of the controls. In neither the rheumatic nor the control groups could any significant differences in skin reactivity be made out between those patients who harbored the micro-organisms and those who did not. The highest proportion of positive skin reactions to the extract of hemolytic streptococcus was found in cases of chorea. Afebrile cases were less hypersensitive, and febrile cases (including those in which fever had been present within one month preceding the test) were least sensitive. Of sixty-six patients of whom a reliable record could be obtained, thirty-one gave a history of sore throats, but only three had an attack of tonsillitis within two or three weeks of admission to the hospital. The authors' results were in agreement with

those of previous investigators who have shown that skin sensitivity increases with age up to 15 years after which no further increase is noted. The allergic skin reaction may be a result of previous infection with hemolytic streptococci. The presence of skin hypersensitivity to intracellular antigens of this micro-organism cannot be regarded as an indication of the special reactivity necessary to produce acute rheumatism on infection. The intradermal reaction does not appear to be of direct diagnostic or prognostic value in cases of rheumatic infection.

Immune Serum in Acute Poliomyelitis.—Smellie emphasizes the fact that the diagnosis of poliomyelitis in its acute or preparalytic stage is an essential criterion for successful treatment by immune (convalescent) human serum. This preparalytic stage presents a chain of symptoms and physical signs which can be recognized. Lumbar puncture, with cytologic and biochemical examination of the cerebrospinal fluid, is necessary to establish the diagnosis and immune serum should not be administered until this has been done. The employment of convalescent serum in the treatment of acute poliomyelitis is founded on sound experimental data in animals. The serum of a person who has had poliomyelitis has been demonstrated to possess high neutralizing properties for many years thereafter. The blood of adults who have not suffered from the disease clinically may also possess neutralizing properties. While the statistical evidence in favor of immune serum is far from convincing, those who have had most experience with this form of treatment feel that a strong case has been made out for its employment and that ample justification exists for its continued and extended use. The place of lumbar puncture in the treatment of preparalytic poliomyelitis has not yet been settled. The withdrawal of sufficient fluid to allow the pressure to return to normal is probably of value in preventing the development of paralysis or at least in modifying its progress. Evidence is accumulating to show that passive immunization against poliomyelitis may be of value as a prophylactic measure.

Cough in Childhood.—Moncrieff states that in considering the possible causes of cough in childhood, the upper regions of the respiratory tract downward should be examined. Acute inflammatory conditions of the nose and nasopharynx are frequently associated with a cough but in such instances it is almost impossible to exclude inflammation of other portions of the respiratory tract, and the cough may have a complex origin. Coughs of pharyngeal origin are common. Most laryngeal disorders are a combination of inflammation and spasm varying from almost pure laryngitis through laryngitis stridulosa, in which the spasm plays a part, to laryngismus stridulus when underlying tetany produces an almost purely spasmodic condition. The harsh, painful, ineffective cough of a tracheitis is a comparatively common sequel to a cold in the head. Inflammation of the bronchi frequently follows tracheitis as the cold spreads down to the chest. Inflammatory conditions of the lung that is chronic inflammatory conditions—nontuberculous fibrosis of the lungs—are common causes of cough in childhood, especially when the cough follows measles or whooping cough. If the origin of the cough has been accurately localized, the treatment becomes relatively simple. For most coughs in children a sedative linctus is best such as 10 minims (0.6 cc) of compound tincture of camphor 10 minims of oxymel of squill, 10 minims of spirit of glycerin and enough water to make 1 ounce (30 cc) for a child of 2 years. The first step in the treatment of coughing is to eliminate or treat the cause as far as possible. This means measures varying from irradiation of an enlarged thymus to evacuation of an empyema. The steam tent in the treatment of respiratory disorders of childhood has a limited field and many drawbacks. In the treatment of

bronchitis many of the drugs used, such as ammonium carbonate, squill and ipecacuanha, have a direct irritant effect on the alimentary tract if used in anything but small doses, and in young children the use of these drugs may lead to gastroenteritis. When the secretion is thick, during the early stages, alkalis are most valuable and a good combination is 3 minims (0.2 cc) of wine of ipecac, 5 grains (0.3 Gm) of potassium citrate, 5 minims (0.3 cc) of compound tincture of camphor, 10 minims (0.6 cc) of glycerin and enough water to make 1 ounce (30 cc.) three times a day for a child of 1 year. Later on a little ammonium carbonate (one-half grain, or 0.03 Gm) may replace the potassium citrate and if much wheeziness is present a few minims of tincture of stramonium should be added.

Mitral Stenosis—Jones analyzed 300 cases of mitral stenosis on clinical lines in order to assess the importance of the history of rheumatic fever and allied conditions in the causation and aggravation of the disease. There is evidence that the disease is commoner in women than in men in the proportion of 3 to 1, and that it occurs at a definitely earlier age in males (50 per cent at the age of 25). Rheumatism is an important etiologic factor. At the most conservative estimate it was the etiologic factor in 80 per cent of the cases. It is probable that 90 per cent is nearer the correct figure in the present series. No other etiologic factor was found present with any degree of constancy. In the majority of the patients the symptoms were similar in type, varying only in degree of intensity. Breathlessness on exertion was the most common complaint, while vague precordial pain not anginal in type was frequently mentioned. Symptoms are often absent until the onset of auricular fibrillation. The actual onset of the fibrillation may be sometimes dramatic, and the patient is able to associate it with some particular strain. Cardiac symptoms may be attributed to some definite occurrence, quite apart from the onset of fibrillation: pregnancy strain, infection and domestic worry. Occasionally a patient presents himself with symptoms of frank disordered action of the heart, and on examination mitral stenosis is found. Symptoms may vary because of some external factor, physical or physiologic.

Treatment of Dementia Paralytica by Diathermy—Graham treated twenty-four dementia paralytica patients by diathermy and obtained a clinical remission in 52 per cent. Present results are superior to those following treatment by malaria. The mechanical control of the hyperpyrexia makes this method of treatment safe. Risk of burns is negligible if ordinary care is observed. Respiratory complications have been a feature and caused one fatality. Owing to the small number of cases treated and the short time that has elapsed since the remissions developed, a definite opinion cannot be given about the value of this method.

Malarialization in Dementia Paralytica—Smith states that dementia paralytica is as prevalent among the population of the Malayan peninsula as among that of Europe. This prevalence is, moreover, even less than it would otherwise be because of the retarding effect of concurrent protozoal infections and the tendency of the Oriental's metabolism toward dermatropic rather than neurotropic lesions in all spirochetal diseases. Dementia paralytica responds much less to malarial treatment in Asia because these neurotropic patients represent the most developed of the cases of syphilis, i. e., cases which have persistently resisted the action of exogenous and endoge-

nous antibodies. It is extremely difficult to obtain effective malarial inoculation in Asiatics of the coolie class who have been brought up in a country where malaria is indigenous and who may be presumed to have acquired some degree of immunity. Of the fifty-six patients treated at the author's hospital, the cases being drawn from all nationalities, all of which were inoculated, one was "cured" (discharged), two were markedly improved (discharged), one was slightly improved, six were not improved, two died of malaria, and forty-two failed to contract malaria, and no improvement was noted among any of these such as might be attributed to "apyrexial malarial therapy." All patients who failed to contract malaria were reinoculated at least once, twenty-nine were reinoculated three times intramuscularly, five were reinoculated four times intramuscularly and ten were reinoculated intravenously after the first intramuscular attempt. The other twelve patients commenced rigors within from seven to eighteen days of the first intramuscular injection with the exception of one patient who was reinoculated after twenty-one days, the original rise of temperature having proved abortive, eleven of these cases remitted spontaneously, and only one, the "cured" case, required quinine. The patients were men and they were selected on strong clinical evidence the diagnosis being confirmed later by the serologic observations before inoculation.

*Facial Paralysis Due to Toxic Inflammation of Geniculate Ganglion. J. P. Findlay.—p. 251

Facial Paralysis—Findlay states that the symptoms of facial paralysis follow the infection of the geniculate ganglion and he describes them as a syndrome. Intense otalgia and tinnitus occur followed later by swelling of the ear, which develops into herpes zoster. The facial paralysis develops and in all the cases that he has seen, it has been a complete facial paralysis of the side involved, commencing at the same time as the herpes zoster. Loss of taste occurs, but he has found this rather hard to establish, although two patients were definite and stated that they had no taste for any kind of food stuffs. The distribution of the herpes zoster is constant: the drum membrane, the walls of the external canal, the external meatus, the cavum conchae, the antitragus, the anthelix and part of the lobule are involved. If the inflammation of the ganglion extends along the nerves into the internal auditory canal, hypacusis follows with nystagmus, vertigo and vomiting, the eighth nerve being involved, deafness with tinnitus occurs, simulating a typical Meniere syndrome. The otalgia varies in intensity and duration sometimes lasting for from seven to ten days, being accompanied by severe noises in the ear. Treatment is either medical or surgical. The facial muscles should be supported. The eye should be watched for any corneal abrasions. Massage of the facial muscles should be commenced at once. Tinnitus and vertigo should be relieved by giving bromides. When inflammation of the ganglion has been caused by a toxic infection from a focal sepsis, this focal infection must be eradicated. If the focal sepsis is not located and removed at once the delay results in a long lasting paralysis.

*Acute Abdominal Syndrome of Peritoneal Irritation by Moderate and Progressive Effusion of Aseptic Fluid. J. Meillère—p. 605

Peritoneal Irritation by Effusion of Aseptic Fluid.—Meillère states that a moderate, slow and progressive effusion of aseptic fluid into the peritoneal cavity causes a peritoneal irritation which manifests itself in an acute abdominal syndrome. The essential elements of this syndrome are a certain degree of nausea with intestinal obstruction, moderate distention of the abdomen with sensitivity to palpation, parietal defense, meteorism more or less obscuring the hepatic dulness and that of the iliac fossas, general fatigue, pale facies and moderate fever. He reports four cases in which this syndrome was observed: three concern a hemoperitoneum and one concerns a sudden production of ascites. The main cause for the production of this abdominal syndrome is the type of hemoperitoneum with progressive inundation by slow bleeding. It may be a postoperative hemoperitoneum, seen most frequently after hysterectomy for fibroma and after extirpation of intraligamentous cysts, a residual hemoperitoneum, seen particularly after splenectomy for rupture of the spleen or after ovariectomy for rupture of tubal pregnancy, or, most commonly, a hemoperitoneum from rupture of an organ. Spontaneous rupture of the spleen produces the most typical abdominal syndrome of peritoneal irritation. At first there is high abdominal pain on slight effort, then an interval of calm, after which the abdominal syndrome of peritoneal irritation develops progressively. If there is no history of trauma, the differential diagnosis involves acute peritoneal infection, acute intestinal obstruction and cataclysmic inundation of the peritoneum. Rupture of the spleen by manifest trauma commonly causes abundant hemorrhage with rapid inundation of the peritoneum and with distinct abdominal signs from the beginning, and is diagnosed by abdominal sensitivity, parietal tension, dulness in the lower part of the abdomen and progressive anemia, but if there is only a moderate oozing of blood, and the inundation is progressive, the abdominal syndrome develops more slowly and assumes the form described by the author. Other forms of hemorrhage from this cause are abundant cataclysmic hemorrhage dominated by anemia, or small localized hemorrhage causing a hematoma. Intraperitoneal hemorrhages from rupture of extra-uterine pregnancy manifest themselves by analogous clinical syndromes. If the hemorrhage is moderate and inundation of the peritoneum progressive, the syndrome is similar to that already described but limited to the pelvihypogastric region.

Traumatic Mercurial Poisoning.—Liebold reports a case of mercurial poisoning, in a nurse, resulting from a traumatic injury to the hand by breaking a thermometer. The question of the possibility of mercurial poisoning from the smallest doses of mercury introduced into the tissues is discussed. The author draws the following conclusions: Injuries as the result of breaking a thermometer are capable of introducing mercury into the tissues and of giving rise to mercurial poisoning. The intensity of the poisoning depends on the localization, degree, duration and method of introduction of the mercury, as well as on the susceptibility of the organism concerned. Even the smallest doses are not to be disregarded. The finer the state of division

of the mercury in the tissues, the greater the absorption and, proportionately, the greater the danger of intoxication. Conservative treatment as well as attempts to scrape out the mercury are usually of no avail. Histologic studies of the infiltrated tissue make it evident that the logical treatment is excision of the tissue involved. A roentgenogram should be taken before and after the operation. Even the smallest amounts of mercury call for excision. Primary closure of the wound is inadvisable. The remaining mercury can be amalgamated by placing a copper wire into the incision. Attempts at squeezing or massaging are injurious, as they lead to a finer division of the mercury particles. Toxic symptoms disappear rapidly after excision of the involved tissue.

Meniscus Operations.—Mandl presents a critical analysis of 400 operations on the meniscus of the knee joint. There were 325 men and 75 women. The ages ranged from 11 to 52 years. The author points out that, while the median meniscus is particularly predisposed to rupture and pathologic changes, the anterior meniscus shows a predisposition to the development of a grating knee and to cyst formation. Ninety per cent of the injuries to the menisci were of traumatic origin, while 10 per cent were non-traumatic. The latter were characterized by primary degenerative changes, the rupture being of secondary importance. In a number of these patients, both menisci of one joint or one meniscus of each joint were found involved. One-sided stress from a particular occupation or sport results in degenerative changes in the cartilage, which in time may lead to a complete rupture. Roentgenologic diagnosis with the aid of a contrast medium has been disappointing. The author advocates an early operation, systematic exploration of the entire joint, removal of inflamed enlarged fat bodies, removal of foreign bodies, and repair of torn ligaments. In the after-treatment the author stresses the earliest use of the muscles, early getting out of bed, active movements and massage. Regeneration of a meniscus was demonstrated in all cases in which the operation was repeated. Of 338 patients followed up for from eight months to ten years, 85 per cent were entirely well and able to resume occupation and sport, and 15 per cent were not cured.

Hemophiloidia Case. W. Kremer—p. 774

Bleeding Breast.—Scherwitz reports his observations on twenty patients having presented themselves at the Bier clinic in the course of twenty-five years with bleeding nipple. On histologic examination, nine of these proved to be instances of a cyst-epithelioma with malignant transformation in two, and five were instances of cystic degeneration of the breast with malignant transformation in one. No histologic examination was made in six. The study of the course of the disease in the twenty patients suggests that the symptom of bleeding alone does not enable one to form an opinion as to the prognosis in a given case. Persistent bleeding suggests the presence of one or more cysts. To produce the symptom of bleeding, the cyst must communicate with one of the larger ducts. The histologic picture cannot be surmised from the bleeding alone. The author believes that a breast with cystic degeneration is particularly predisposed to malignant transformation. He views cyst-epithelioma as a benign tumor with, however, a pronounced tendency to malignant degeneration. Consideration of all the signs and symptoms rather than of the bleeding suggests the proper treatment. The author does not subscribe to the dogmatic insistence of Klose on a radical removal of the breast with dissection of

the axillary glands based on his assumption that a bleeding nipple signifies a precancerous state. The author favors a more conservative plan such as the removal of palpable lesions by the method of Warren, or a mastectomy followed by plastic fat substitution of Lexer. A careful histologic study of all removed tissues is essential in order not to overlook a malignant condition.

Mineral Salts in Ileus—Eggs showed that in experimental ileus in dogs the mineral ions in the blood undergo a characteristic change, namely, a lowering of chlorine ions and a fall in alkali reserve. There is a striking lowering of potassium ions, while calcium ions remain practically unaltered. Sodium ions did not in every instance run a parallel course with chlorine ions, as originally maintained by Haden and Orr. The author calls attention to the fact that short-circuiting bile and pancreatic secretion in experimental ileus gives a milder much different picture without a lowering of chlorides. Introduction of the contents from an obstructed loop into the intestine of a healthy animal through a fistula produces a typical picture of ileus, but without lowering of chlorides. The loss of minerals is explained by the confinement of bile and pancreatic juices within the obstructed loop. Because of a restricted area of absorption as well as because of vomiting there ensues a loss of minerals from the bile and the pancreatic secretion. If the latter are short-circuited so as to be introduced into the bowel below the obstruction, hypochloremia does not develop. Loss of sodium ions and of chlorine ions on the part of the liver, an organ normally retaining large amounts of these ions and participating in the maintenance of mineral balance, exposes it even more to the damaging effect of the toxins produced in ileus and further impairs its function. Thus, a sort of a vicious circle is established. The effect of the administration of salt solution therefore is to be considered more than a symptomatic treatment. On the other hand, the author points out that administration of salt solution does not affect the hypothetic toxin of ileus directly but that it neutralizes its effects, the loss of minerals and the loss of water.

Gangrene of Lower Extremities—Vogel reports 314 cases of gangrene of the lower extremities treated in Payr's clinic (Leipzig) from 1912 to 1931. Of these, 197 were of arteriosclerotic and 117 of diabetic origin. The incidence in men was twice that in women, 215/99. The average age for the arteriosclerotic group was 69.2 years, while for the diabetic group it was somewhat lower, 62.8. The combined mortality amounted to 58.2 per cent, 60.7 per cent for the diabetic group and 56.4 per cent for the arteriosclerotic group. The major amputations resulted in approximately the same mortality, 51.8 in the arteriosclerotic group and 57.3 in the diabetic group. The immediate mortality after these operations was exceptionally low, more than half of the fatalities resulting from complications setting in after the seventh day after the operation. These were pneumonia, cardiac failure, sepsis, spread of gangrene and coma. The highest mortality occurred after amputation of the thigh. The level of the amputation was influenced by the condition of the circulation and, in the case of moist gangrene, by the spread of infection. The introduction of insulin was rather disappointing in its effect on the treatment of diabetic gangrene as compared with operations on diabetic patients for other causes. The mortality rate in fifty-six patients before the insulin era was 56 per cent, while in thirty-one patients treated with insulin it amounted to 58.1 per cent. The mortality from coma, sepsis and spread of gangrene could not be influenced by prolonged preoperative treatment with insulin.

Effect of Arteriovenous Aneurysm on Circulation—Fick's study is an attempt to explain in animal experiment the mode of production of the clinical phenomenon occurring in arteriovenous aneurysm, namely, rise of blood pressure and simultaneous slowing of the pulse of the afferent artery on compression of the aneurysm. Histologic studies of the afferent artery in one of the author's clinical cases demonstrated extensive degenerative changes. The cause of these is not clear. It

suggests that the method of treatment of the aneurysm by compression is not safe, since rupture of a degenerated vessel may take place. Profound morphologic and functional alterations in the entire blood vascular tree are to be noted in the clinical observations in cases of arteriovenous aneurysm. The veins undergo early dilatation and the arteries develop pronounced degenerative changes only after a number of years, but these are in all likelihood irremediable. The author demonstrated in dogs in which he created arteriovenous fistulas, that with shunting of the arterial blood into a vein the general blood pressure fell. A rise took place after a short period of time, but the pressure did not reach the original level. Sectioning of the vagus and the sympathetic on both sides as well as sectioning of the spinal cord did not interfere with the phenomenon described. Apparently nervous influences are not concerned in its production. The mode of action appears to be hemodynamic, resulting from the sudden termination of a condition which lowers the blood pressure by diverting a certain amount of arterial blood into the venous stream. The pulse became slowed simultaneously with the rise in the blood pressure, and this was apparently not the result of the congestion of the right side of the heart. It was probably the result of a rise in the blood pressure. Dilatation of the veins leads in course of time to dilatation of the right side of the heart and to hypertrophy of the right ventricle. The remote effects of an arteriovenous aneurysm did not depend on its localization, the important factor being the amount of arterial blood shunted into the venous stream. The development of a collateral circulation is an indication for surgical removal of the aneurysm in order to obviate further damage to the vascular tree.

Sequelae of Tuberculosis of Bronchial Lymph Nodes—As the most essential clinical symptoms of tuberculosis of the bronchial lymph nodes, Eliasberg considers those that are produced by pressure on the trachea and on the large bronchi. She points out that the resonant cough and the expiratory panting are caused by this pressure and she advises a tuberculin test whenever these symptoms are present. She thinks that it will prevent serious errors, such as tracheotomy or intubation, because the respiratory symptom is mistaken for a diphtheritic stenosis. If the compression of the trachea and of the bronchi by the tuberculous lymph nodes becomes more pronounced, other disturbances may become manifest. Pronounced compression and narrowing of the trachea or of the large bronchi lead to a disturbance in the air intake which in turn causes an increase or a decrease in the air content of the lung. This contradictory behavior becomes understandable when the pathogenic mechanism is considered. If the compression by the tuberculous lymph nodes permits the normal air intake but hinders the normal expiration by a valvular action, emphysema develops in that portion of the lung which is supplied by the compressed bronchus. The clinical manifestations of compression emphysema are an

inflation of the affected side of the thorax, a more or less pronounced boxy note and a weakened respiratory sound, the character of which is usually difficult to estimate on account of the stridor. The roentgenologic aspects are quite typical. Roentgenoscopy reveals, besides the causal tumors of the lymph nodes, a considerable increase in the air content of the lung on the side of the diseased lymph nodes. As a result of the increased pulmonary volume the intercostal spaces appear wider the diaphragm is lowered and flattened and the respiratory motility is reduced on the diseased side. The mediastinal organs including the heart and the large vessels are more or less displaced toward the healthy side. In the second form, the passage of air to a lung or to part of a lung is hindered. This results in collapse because the decreased pulmonary volume and the decreased intrathoracic pressure force the diaphragm upward and draw the mediastinum into the space of the collapsed lung. A compensatory emphysema develops in the healthy lung. Discussing the treatment of the two sequelae the author emphasizes that all therapeutic measures must aim at freeing the way for the air stream by decreasing the swelling of the lymph nodes and of the bronchial mucous membrane, if the latter is involved. She recommends saline purgatives intravenous injections of hypertonic solutions and low fluid intake. Atropine and an ephedrine preparation may be given in order to limit secretion. Sedatives are advisable since the dyspnea becomes exacerbated by restlessness. Artificial pneumothorax has been recommended for the treatment of atelectasis, in order to increase the lowered intrathoracic pressure and to counteract the mediastinal displacement. Carbon dioxide respiration has been recommended because it deepens respiration, increases the motility of the bronchial muscles, facilitates expectoration and decreases the swelling of the bronchial mucous membrane.

Treatment of Enuresis.—Feer discusses the involuntary evacuation of the bladder that takes place during sleep. This form of enuresis is not the result of a local impairment of the urinary apparatus but is rather a functional neurosis. It occurs most frequently in psychopathic children. In nurslings the evacuation of the bladder is still a reflex mechanism, but later this reflex action is replaced by a voluntary mechanism, the result of training the discipline first acquired during the day gradually becomes also effective during sleep. Enuresis is largely caused and prolonged by indifference, lack of will power, coddling, and the desire of the child to be noticed but also by punishment and unjust treatment. The author considers onanism of no importance. He classifies the patients in two groups: the careless and the neuropathic types. For the first or smaller group he recommends training of the bladder by making the child urinate on request several times during the day and making the child, at times, control its urge for evacuation for about five minutes. He also suggests treatment by electricity in the course of which the electrodes are applied over the bladder and the perineum. If, after one or two treatments, there is no improvement, the strength of the current could be somewhat increased to the point of producing pain. The second or neuropathic group of patients is much more numerous than the first group. These children require encouragement, and their self confidence and ambition should be stimulated. The author ascribes great value to gymnastics, which were recommended by Thure and Brandt. The diet is important. It should be largely vegetarian and the salt intake should be low. The vegetarian character of the diet makes unnecessary the administration of sodium bicarbonate, recommended to counteract acidity, to which an irritating effect on the bladder has been ascribed. In order to prevent potassium storage and the resulting chlorine hunger that necessitates late evacuation of the bladder, the eating of potatoes should be restricted. The evening meal should not include too much fluid. Atropine is often a valuable aid, but the author found strychnine ineffective. Daily persuasion by the physician is also important, but to render it effective the patient should be hospitalized and if possible, should have a private room.

Waterhouse-Friderichsen Syndrome.—Glanzmann considers massive hemorrhage in both suprarenals, discovered in the course of postmortem examination, the most characteristic sign of the Waterhouse-Friderichsen syndrome. In the last few hours before death the symmetrical apoplexy of the suprarenals is accompanied by an extensive cutaneous purpura. The author reviews the literature of the syndrome, and describes his case.

The syndrome develops in children between the ages of 2 months and 2 years. The earlier history is generally one of complete health. In rare instances prodromal symptoms, such as fatigue, paleness and slight increase in temperature, are observed a day previous to the sudden onset, which begins with vomiting, two or three thin stools, attacks of convulsions with tonic-clonic spasms and high temperatures. A few hours later a cutaneous purpura develops and collapse follows. The trunk is burning hot, while the extremities are cool. The pulse is frequent, sometimes over 200, but soft and hardly perceptible. Paleness of the face alternates with cyanosis. The respiration is accelerated, superficial and occasionally irregular. The child becomes somnolent, apathetic and finally comatose. Death may be preceded by convulsions and by a sudden decrease in temperature. Because of the rapid course of the disturbance the blood picture has only rarely been studied, but the author's case revealed three pronounced changes: (1) progressive thrombopenia, (2) great changes in the white blood picture, particularly a decrease in the polymorphonuclear forms, and (3) appearance of normoblasts. Because the changes in the blood resemble greatly those of purpura variolosa, a septic infection is considered the pathogenic factor of the syndrome, although exact proof in the form of positive blood cultures is still lacking. The suprarenal and cutaneous hemorrhages are probably the result of a combination of capillary toxicosis and of thrombopenia. That the cutaneous purpura is absent in some cases of apoplexy of the suprarenals is probably due to the fact that the patients die before it becomes manifest. The author states that the treatment by administration of epinephrine is not sufficient, because the suprarenals are involved in their entirety and extract of the cortex of the organs must also be given. However even this therapy promises little result in view of the serious septic infection in the Waterhouse-Friderichsen syndrome.

Rectal Administration of Milk in Nurslings.—Hamburger states that in the treatment of two breast-fed infants with severe pyloric vomiting and with limited gastric capacity he administered by rectum, that part of the mother's milk which could not be taken by mouth. Since the cure of these children took a favorable course, the author decided to try this treatment in children with pyloric stenosis in whom treatment with atropine and with sedatives did not check the vomiting. The nutritive clyster was given from three to five times daily in quantities of from 40 to 60 Gm. The clinical histories of children in whom this treatment was employed indicate that during the period of rectal administration of human milk there was an increase in weight, and the other symptoms disappeared. The author does not wish to give the impression that this is a universal method without failures. The treatment failed when it was continued only for a short time in cases in which the serious general condition did not permit an expectant attitude and a continuation of conservative measures. Attempts to use cow's milk instead of human milk revealed that the favorable action of human milk is not primarily the result of the administration of the components, such as water, salts, lactic acid or protein but is rather due to its specific composition which makes possible a digestion similar to that in oral administration. The author further relates roentgenologic studies on the retrograde ascension of human milk and discusses particularly the action of the ileocecal valve in antiperistalsis. He cites the studies of other investigators, which indicate that in young children this valve does not yet close, a fact which would provide a favorable condition for nutritive clysters.

Diagnosis of Disorders of Mesenteric Lymph Nodes.—Karger points out that the mesenteric lymph nodes of children may be the cause of pains and that some of the so-called umbilical colics may have their origin in pathologic processes of the mesenteric lymph nodes which may be enlarged or otherwise affected, although the usual methods of clinical examination do not reveal it. Numerous authors admit that lymph nodes of walnut size have escaped them on palpation. The reason for this is probably the softness of the nodes, while their anatomic relations are such as to make direct palpation hardly possible because they are situated in a movable mesentery or on the radix mesenterii separated from the palpating fingers by the intestine. Thus it becomes clear that an indirect method has to be found. The author shows that by means of the deep gliding palpation, according to Glenard and Hausmann, it is

possible to detect changes in the mesenteric lymph nodes indirectly by pressure pain. If inflamed lymph nodes are on the left end of the radix mesenterii, it is possible to press them against the hard foundation of the vertebral column and, even if they cannot be palpated as nodules it is frequently possible to produce a pressure pain. The direction of the palpating fingers should not be vertical but rather from lateral to medial, toward the vertebrae, and the palpating hand should enter laterally from the outer rim of the rectus muscle. Because of the elasticity of the abdominal walls of the child, it is always possible to approach the vertebral column in this manner except when there is ascites or pathologic tension of the abdominal walls. The pressure pain indicates of course only a pathologic process in the region of the radix mesenterii. For the diagnosis of tuberculosis of the mesenteric lymph nodes, it is necessary to test for tuberculin susceptibility, to consider the duration of the pains, and to watch for other symptoms, on the basis of which acute appendicitis can be excluded. Old processes of lymph nodes with shortening of the mesenterium can frequently be detected by pulling on the intestine without pressing it downward, for this imitates the mechanism that leads to spontaneous pain. In cases in which a pathologic process of the mesenteric lymph nodes seemed probable the author frequently tried high voltage roentgen therapy, and often the pains disappeared after the second or third irradiation. In a large number of cases in which abdominal pains existed but in which mesenteric pressure points were not detectable, irradiation was ineffective and a considerable number of umbilical colics remain unexplained.

Radical Operation of Inguinal Hernia—Moszkowicz states that, although many improvements have been suggested for Bassini's radical operation of inguinal hernia, none of these have replaced the original Bassini method. Only Schmieden, who called attention in 1929 to the weak points of the Bassini suture and made suggestions for its improvement, was given some consideration. His method, tried by many surgeons, sees in the spermatic cord the main obstacle for an exact suture of the inguinal canal and suggests taking the spermatic cord and the testis from the scrotum and leading them through a special opening in the transverse abdominal muscle. The author employed this method but did not find it entirely satisfactory because it makes the intervention considerably more difficult although not essentially more reliable than Bassini's method. The author describes a radical method that follows more closely the one recommended by Bassini and gives more attention to the "weak" points than was done formerly. His method aims to remove, as far as possible, the neck of the hernial sac from the spermatic cord, and to lead them in opposite directions, the neck of the hernial sac inward and upward and the spermatic cord outward and upward. He thinks that a renewed protrusion of the peritoneal sac toward the inguinal canal is thus made practically impossible. The displacement of the spermatic cord under the skin, which is feared by many, has been found to be without danger. The author thinks that this may be the result of leaving the spermatic cord in the cremaster sheath and putting in an additional protective layer by a special catgut suture of the subcutaneous fat. In direct inguinal hernia, in which the danger of relapse is greatest, he does not open the hernial sac but makes at the neck of the sac a purse string suture of the transversalis fascia, into which the sac is invaginated. After this suture is made the patient is asked to cough, in order to ascertain whether the sac no longer protrudes. The further course of the operation is the same as in other cases. The author admits that his technic is not entirely original and that all its different phases have been described elsewhere. He has

combined them in a unified method and therefore feels justified in reporting it. His method has been effective in the treatment of relapses.

Etiology of Osteochondritis Coxae Juvenilis—Hilgenreiner shows that, besides congenital luxation and subluxation of the hip, there are other inhibitory malformations of minor degree that occasionally become manifest in the nonluxated joint during the first year of life under the form of a considerable retardation in the development of the center of ossification of the epiphysis, or in a pronounced hypoplasia of this center. Since the retardation in the observed cases of congenital luxation was always followed by a deformity of the head of the femur, that is, by an early form of Perthes' disease, the assumption is justified that spontaneous Perthes' disease of older children is the result of a similar inferior condition of the articulating bones, the later manifestation being the result of the slight degree of the malformation and of the absence of the early causal factor (luxation treatment).

*Influence of Moor Baths on Blood Pressure. H. Guthmann and L. Hess—p. 55

Therapy of Pyelitis—Stark discusses postoperative inflammations of the renal pelvis and their forms occurring during and after labor, during gravidity, after menstruation or without demonstrable cause. Of seventy-two patients with inflammations of the renal pelvis, fifty-nine were successfully treated with medicinal and dietetic measures, whereas thirteen required local therapy. Of the latter, three were given one or two irrigations of the renal pelvis without continued catheterization, eight were treated by continued catheterization with irrigations, while two were catheterized but were not given irrigations. Local treatment was resorted to because the patients did not react to the medicinal and dietary therapy or because threatening general symptoms existed or the condition presented a chronic character. Irrigation alone without permanent catheterization influenced pyelitis favorably, but the disorder lasted longer than was the case when irrigation was combined with continued catheterization. The author thinks that the failures of local treatment in pyelitis can be traced to the fact that irrigation without catheterization was employed, so that the urinary stasis was only temporarily counteracted, or to the fact that complications of pyelitis existed, which simulated a failure of the therapy.

Influence of Moor Baths on Blood Pressure—Guthmann and Hess found that a hot moor bath decreases the systolic pressure. This decrease is more pronounced in medium warm baths than in really hot baths. The authors were unable to corroborate the increase in blood pressure which a number of other investigators claimed to have observed as a result of hot moor baths, for neither the average values nor the individual values showed an increase in the majority of patients. The so-called terminal increase of the blood pressure becomes more noticeable as the temperature of the bath increases. The diastolic blood pressure decreases immediately following the beginning of the bath. In warmer baths and in full baths the decrease is somewhat slower. The amplitude is temporarily increased during the bath. This increase becomes more pronounced as the bath gets warmer. Less hot, full moor baths exert the same influence on the blood pressure as hotter half moor baths. Thus the moor baths can be individualized by giving a half or a full moor bath, or by changing the temperature and the duration of the baths. The authors' observations prove that in women with normal heart action a series of moor baths does not alter the blood pressure.

Intra-Uterine Therapy in Endometritis and Abortion—The action of intra-uterine carbon therapy, which, according to Geller and Schuster, has been employed for a number of years in cases of endometritis and of febrile abortion, is primarily a physical one due to its adsorption capacity by which the surface of the tissues is dried and which deprives the bacteria of a suitable growth medium. Bacteriologic studies have shown that the chemotherapeutic action of carbon is slight because carbon does not inhibit bacterial growth in mediums such as blood or serum. Consequently it has seemed desirable to find an intra-uterine treatment in which the adsorption capacity of carbon could be complemented by chemotherapeutic action without producing local irritation or general toxic effects. Since, in veterinary medicine, suppositories containing silicic acid and an acridine hydrochloride derivative were found helpful in such conditions as streptococcal mastitis, metritis and secondary retention, the authors studied the sterility and the antiseptic action of these suppositories. They found the preparation to be of good antibacterial action, and since it contains silicic acid, a well tolerated adsorbent of the greatest surface activity, they decided to try the suppository in human intra-uterine therapy. The therapeutic results will be reported later.

Increase in Tubal Pregnancy and Its Causes—Bernhard has studied the histories of 645 cases of tubal pregnancy observed at the Basel women's clinic from 1895 to 1930. He agrees with other investigators that in recent years there has been a considerable increase in extra-uterine, particularly tubal, pregnancies. But in contradistinction to the numerous authors, who emphasize only one etiologic factor, he stresses that there are many causes. He mentions (1) increased gonorrheal morbidity, (2) greater frequency of abortion (3) wider use of contraceptives, and (4) increase in inflammatory processes such as develop following chronic appendicitis. He does not consider the relatively rare pathologic processes, such as carcinoma, tuberculosis and benign tumors of the uterine tubes, a cause of the increased incidence of tubal pregnancy, and he thinks that hypoplasia of the genitalia and neuroses of the sympathetic nervous system have only a slight significance. He admits that effective measures to counteract the further increase are difficult but not entirely hopeless. Especial attention should be given to the prophylaxis and treatment of inflammatory, particularly gonorrheal, processes, and to instruction on the hygiene of marriage and the use of contraceptives.

Magnesium Therapy in Angina Pectoris—In patients with angina pectoris, in whom spasmolytic medicaments failed or accomplished only temporary improvement Bandmann resorted to magnesium therapy. His object was not to counteract the anginal attack as is done with glyceryl trinitrate or amyl nitrite but rather to decrease the frequency of the attacks. The patients were given intravenous injections of a sterile 10 per cent solution of magnesium chloride three times each week. The initial dose was 5 cc, which was gradually increased to 10 cc. The maximal number of injections was twelve in the majority of cases. The injections were given slowly and were always tolerated well, except that the patients had a sensation of intense heat, which first became noticeable in the tongue and mouth and then gradually spread to the lower extremities. But this sensation always disappeared rapidly, and the feeling of heat was less pronounced when the injections were given slowly. All other medicaments were discontinued during the magnesium therapy. Of the fifty patients treated in this manner, twenty-nine showed a considerable improvement of their anginal symptoms and a decrease in the frequency of the attacks. There was only a temporary improvement in eight instances, and the therapy failed in twelve. The best results were obtained in patients in whom the blood pressure was considerably increased. Nineteen of twenty-three of this class of patients showed considerable improvement in their anginal troubles, three showed slight improvement, and the treatment failed in one. This patient had received his injections at irregular intervals. Together with the anginal symptoms, the symptoms of hypertension (headaches, dizziness and insomnia) also showed improvement in most cases, although a decrease in blood pressure was absent. Of the twenty-seven patients with normal pressure, only eleven showed a marked and five a slight improvement whereas eleven were influenced hardly at all. On the basis of his experiences the author recommends magnesium therapy for patients with angina pectoris in which medicinal therapy does not have the desired effect.

Insulogenic Infantilism—Fliederbaum defines insulogenic infantilism as an inhibition of growth and a disturbance in the development of secondary and tertiary sex characters, produced by endocrine insufficiency of the pancreas. Although the cases observed by him were always accompanied by diabetes, he admits that there may be cases of infantilism without diabetes, produced by insufficiency of the islands of Langerhans. The anamnesis of the patients with insulogenic infantilism reveals that before or during puberty symptoms of diabetes, such as increased appetite, thirst, cutaneous itching, emaciation and polyuria, became manifest. The second symptom is inhibition of the physical development. As soon as the first signs of severe diabetes become manifest, the growth process ceases. The third symptom is disturbance in the sexual development. If the diabetes becomes manifest before puberty, there is hypoplasia of the genital organs. Other characteristic signs of the patient's insulogenic infantilism are a childish and youthful appearance and changes in the bones. Roentgenologic examination reveals lack of coalescence between epiphysis and diaphysis of the long bones and absence of foci of ossification in the epiphyses. The author differentiates insulogenic infantilism from Loraine's infantilism (chétivism of Bauer), from Brissaud's thyrogenic infantilism, from testogenic infantilism, from disturbances of other endocrine organs, and from the form of infantilism produced by hyperfunction of the suprarenal cortex. Discussing the etiology and pathogenesis of insulogenic diabetes, the author points out that, in addition to the beta cells of the islands of Langerhans (which influence the carbohydrate metabolism), the alpha cells, which exert a trophic influence on the organism, are probably involved. The prognosis is largely dependent on the severity of the diabetes and on the therapeutic action of insulin. In one of the related cases a systematic insulin therapy, continued for one year, resulted in a slight increase in growth and also stimulated the sexual development.

Diagnosis of Angina Pectoris by Means of Electrocardiogram—Scherf and Goldhammer state that out of forty patients, who complained of burning, pressure or pain in the cardiac region, thirty-two showed, after the work test, marked

changes in the ST deflection and often also in the T wave and in the QRS complex. The changes were always of the nature of those observed in myocardial impairment. In nine of the thirty-two cases of ambulatory angina pectoris it was possible to register the electrocardiogram also during a spontaneous attack, and the changes observed in these electrocardiograms were essentially the same as those observed after the work test. The electrocardiographic changes were largely independent of the pain. Occasionally they appeared simultaneously with the pain but quite frequently they developed later and disappeared later than the pain, the pressure or the burning sensation. After the work test, they frequently developed without pain or other unpleasant sensations. In patients with angina pectoris it was sometimes sufficient to bend the knees several times in order to produce a lowering of the ST deflection but there was no pain. On the other hand electrocardiographic changes were sometimes absent even when there was severe pain. When the work test was made following medication with glyceryl trinitrate the electrocardiogram frequently showed only slight or no changes. Glyceryl trinitrate administered immediately after work produced prompt disappearance of the pains but the electrocardiographic changes persisted for a time. The administration of phenobarbital, quinidine, atropine or other preparations frequently resulted in a considerable improvement so that the work test was well tolerated and the electrocardiogram showed no abnormalities. In a young person with a mild endocarditic mitral stenosis and with slight insufficiency of the aortic valves who occasionally complained of pains in the cardiac region the work test was followed by the typical electrocardiographic changes, but after a short treatment the pains as well as the electrocardiographic changes vanished. A patient with mesaortitis and with slight insufficiency of the aortic valves developed, without apparent cause after the slightest exertions severe attacks of anxiety (without pain) or he had a feeling of pressure in the cardiac region. The complaints were accompanied by a lowering in the ST deflection but they disappeared immediately following medication with glyceryl trinitrate. There was no increase in the blood pressure which was occasionally reduced. The necropsy corroborated the diagnosis marked stenosis of the orifice of the coronary arteries. On the basis of this report the possibility of diagnosing such cases during life is pointed out. Because in fifty-six patients with severe heart disease (mitral defects, aortic defects, hypertension muscular impairment) the electrocardiogram that was taken after the work test did not show the changes observed in the first discussed patients the authors consider the described changes indicative of a metabolic disturbance in the cardiac muscle the result of a decreased blood perfusion (anoxemia accumulation of abnormal metabolic products).

Treating Hemolytic Shock of Blood Transfusion.—Hesse and Filatov demonstrated in a previous work that hemolytic shock caused by introduction of hemolyzed or incompatible blood was accompanied by a fall in blood pressure and by a spasm of the renal arteries that the spasm of the renal arteries was of central origin that it paralyzed renal function and that it was the cause of death. The characteristic clinical symptom of severe lumbar pain was interpreted as the result of spasm of the renal arteries. The authors demonstrated in animal experiments that immediate transfusion with compatible blood relieved the arterial renal spasm and saved the animal. Opportunity to verify the efficacy of this method presented itself in their clinic and is the subject of the present communication. A woman, who belonged to blood group O was given by

mistake a transfusion of conserved blood from group A. After the introduction of 30 cc. of the blood, the patient became agitated and complained of headache and of severe pain in the lumbar region. The transfusion was discontinued. The lumbar pain became agonizing and the patient developed a marked pallor of the face, a fast pulse and sweating and rectal tenesmus. Eight minutes after discontinuance of the transfusion a new transfusion with compatible blood was begun. There was improvement in symptoms after the infusion of 25 cc of blood and the backache was no longer experienced after the infusion of 100 cc. The introduction of 250 cc made all the symptoms of shock disappear and the blood pressure rose to 132 mm. No effect on the kidney function was evident. The urinary output increased daily and save for a trace of albumin the urine which previously contained red cells and hyaline casts was free from abnormal constituents. Hemoglobinuria could not be established. The authors add the observation made in animal experiments as well as in the case of hemolytic shock in their patient that the venous pressure was markedly raised. Shortly after the infusion of incompatible blood there was a free flow of blood from the cannula. This phenomenon was no longer observable after the infusion of compatible blood. The authors feel justified in assuming that, in their method of immediate transfusion with compatible blood, they have found a means of saving patients from the results of a severe hemolytic shock.

Whooping Cough.—Baksht compares the results of treatment of whooping cough with intramuscular injections of ether with that of injection of combined streptococcus vaccine. There were 177 children in the first group and 269 in the second. Ether was injected in doses of from 0.2 cc. to 3 cc., depending on the age of the child. Ether was given in a 20 per cent solution of camphor liniment into the muscles of the buttock on alternate days the number of injections varying from one to five. Local necrosis occurred once. The streptococcus vaccine was injected on alternate days the number of injections not exceeding four in any one case. The author states that ether injections had a favorable effect on the course of the disease. The number of attacks was diminished and the spasmodic cough was changed after one or two injections to a catarrhal productive cough. The vaccine injections not only diminished the number and the severity of the coughing spells but frequently brought about cessation of the spasmodic attacks thus shortening the duration of the disease. The earlier the treatment was commenced with either method, the more definite were the results. The frequent complications of whooping cough, pneumonia and bronchitis were favorably influenced by either method. Children in whom the treatment was instituted before the complications developed did not develop them subsequently. In view of the relatively small number treated, the author hesitates to state that the method is capable of definitely preventing these complications. Of the two, the vaccine method gave the better results. The course of the disease was shorter and the injections were less painful.

CHRONIC NONSPECIFIC NEPHRITIS

CLINICAL OBSERVATIONS ON FORTY CHILDREN WITH
RESULTS OF TREATMENT ON FULL DIETS

C A ALDRICH, M D

WINNETKA, ILL

AND

H H BOYLE, M D

CHICAGO

Our purpose in this report is to record our experience with chronic nonspecific nephritis from the standpoint of its clinical manifestations and treatment. The use of the term "nonspecific" nephritis is, we admit, not ideal and we hope not permanent, but it is the best name we could think of to indicate our present concept of the condition. One might choose from the literature any one of the many names that have been applied to it, such as chronic diffuse nephritis, chronic glomerular nephritis, chronic glomerulotubular nephritis, glomerular nephritis with nephrotic component, or others, but all these terms have the objectionable feature that they stress the anatomic location of supposed lesions in the kidneys and, therefore, represent diagnostic guesses that are unnecessary. We feel that the adoption of clinically descriptive terms in classifying disease in living patients is a move toward clearer thinking. When it has been clearly shown that a certain clinical picture always accompanies a specific anatomic lesion it may be justifiable to adopt an anatomic terminology, but even then we fail to see its purpose. An etiologic nomenclature is more serviceable. Although it may be imperfect, the term nonspecific implies, truthfully, that we do not know the cause and is intended to include the implication that a more accurate name may supplant it when justified.

The material on which this report is based consists of forty patients, all but one of whom were seen in the nephritic service at the Children's Memorial Hospital, and all of whom were cared for by us between the years 1920 and 1932. The diagnostic criteria by which these patients were separated from other nephritic patients are so clear that practically no exceptions have been made. Since all these patients manifested all the important diagnostic features, they may be described as comprising a sharply cut clinical group. All presented the following clinical signs and laboratory manifestations at some time in the course of their illness: (1) edema, (2) arterial hypertension, (3) increase in the nonprotein nitrogenous constituents of the blood, (4) hematuria, (5) marked albuminuria,

(6) cylindruria, and (7) a rapidly fatal or chronic course. It should be emphasized, however, that these patients did not all show all these abnormalities all the time. Since this paper attempts to report a personal study of the clinical progress of a large number of patients with chronic nephritis over a period of years, it is unique (chart 1).

LITERATURE

We have found no reports in the literature which result from the prolonged observation of a series of patients with this type of nephritis. Among the first papers on chronic nephritis in childhood to appear were those of Gull and Sutton¹ in 1872, and of Guthrie² in 1896. Sawyer³ in 1903 reported twenty-eight cases of chronic nephritis and later⁴ listed forty-six cases in tabular form. From his brief clinical description it would appear that these were instances of what would now be termed renal infantilism or childhood nephrosclerosis. Greene⁵ also reported cases which we believe belong in this classification, which was thoroughly reviewed recently by Mitchell.⁶ It is quite likely that some of Greene's patients may have had syphilis with nephritis.

Decker,⁷ Heubner⁸ and Berkley and Lee⁹ each report a case of malignant hypertension in a child. Heubner cites his as occurring once in seventy-three instances of nephritis. None of our cases could be so classified.

If one were to judge from the literature of the last two decades, it would appear that chronic nephritis frequently ensued on acute hemorrhagic nephritis, a conclusion that we have reason to doubt. James¹⁰ reports sixty-seven cases of acute nephritis, nine of which terminated in chronic disease of the kidneys. He noted a tendency to exacerbations with intercurrent infections. Hill¹¹ considered that acute nephritis might be followed by subacute or chronic nephritis. Heubner,⁸ who gives a somewhat elaborate classification of chronic nephritis, considers that almost all cases

This work would have been impossible without the most efficient sort of cooperative work by the nursing staff and the Social Service Department of the Children's Memorial Hospital.

in childhood may be traced to an infection Morse¹² says, "It [chronic nephritis] is almost invariably the result of a previous acute attack." We would like to point out at this time that, of course, there has to be an onset to any chronic disease and that, if the first attack is considered to be acute nephritis, all chronic cases must follow acute nephritis. The point we are anxious to clarify is whether true instances of typical postinfectious nephritis result in chronic nephritis. It may well be that in this antecedent acute infection we have a differential point useful in separating benign from chronic or sclerosing disease. We are not sure, from an observation of 300 cases of nephritis, that chronic disease often follows the postinfectious type.

However, James¹⁰ reports nine cases of chronic disease which followed postscarlatinal nephritis. Calvin and Rosenblum¹³ report two, the symptoms of which are similar to ours. Hill,^{11a} DeBuys¹⁴ and Boyd,¹⁵ who discuss symptoms, all agree that acute exacerbations are often coincident with infectious processes. All feel that the prognosis is grave. Hill¹⁶ describes cases which he calls a "mild type." He feels that function tests aid in the prognosis. The treatment has

there is not sufficient evidence to prove that postscarlatinal nephritis is a forerunner of adult nephritis and concludes that there is probably no relationship between childhood and adult renal disease. All books stress the importance of protein restriction and removal of foci of infection in the treatment.

Guild¹⁹ has recently reviewed thirty-four cases of acute hemorrhagic nephritis, and, on examination twelve years after the acute disease, she found all patients well and leading a normal life except one who had rheumatic heart disease. None showed renal impairment in function tests. One boy died four years after his nephritis and was examined post mortem. There were no gross or microscopic abnormalities in the kidneys. This work tallies with ours in that we fail to find that acute postinfectious hemorrhagic nephritis commonly leads to chronic disease.

DESCRIPTION OF THE CLINICAL COURSE

It is difficult to make any sweeping statements concerning the clinical course of any disease that exhibits as varied a picture as does this one, but certain facts stand out so prominently and are so often misunder-

* These infections are not necessarily the cause of the nephritis; the authors think it quite likely that they are a result of it.

not been stressed, owing undoubtedly to the bad prognosis, but Morse¹⁷ discusses the indications for Edebohl's decapsulation operation. Evidently the value of this procedure has not stood the test of time, for it is seldom resorted to now.

Pediatric textbooks devote considerable time to this subject and the accounts are quite similar, so that individual references need not be made here. Most authors agree that chronic nephritis may appear insidiously without antecedent disease but stress the influence of acute hemorrhagic nephritis as an etiologic factor. Hoobler¹⁸ quotes the literature to show that

stood that they need clarifying. It may be said that as a rule these children presented all the clinical signs and laboratory manifestations enumerated during the early stages: edema, hypertension, increase in the nonprotein nitrogenous constituents of the blood, hematuria, marked albuminuria, and cylindruria. If death did not occur during the first few months, these manifestations fluctuated widely in severity, tending toward progressive disability (chart 2). After a period of years unless intercurrent infection caused death, renal insufficiency dominated the picture, and the patient died of true uremia often combined with or precipitated by marked acidosis. This fluctuating course was often sharply punctuated or terminated by relapses due to cerebral complications or coincident with intercurrent infections. While using the low protein diet we had never seen the process brought to a standstill, all patients remaining chronic invalids. With changes in treatment later to be described, how-

ever, we have witnessed a few apparent recoveries which are most encouraging. In order to present our observations in an orderly manner, we shall consider the salient points individually.

1 *The Onset*—In the majority of instances, the disease came on insidiously with presenting symptoms of edema, albuminuria and hematuria. Five patients gave a definite history of acute preceding infection, although we cannot be certain that nephritis did not

edema in this "dry" stage in patients who formerly puffed up with each minor ailment. We feel that it should be emphasized again that few of these patients failed to show edema relatively early in the disease and that several of them were without it during the entire latter part.

3 *Hypertension*—This sign, too, was usually present in the early stages and fluctuated to a marked degree. In general, it subsided after each exacerbation to a point in or just above the upper range of normal. Unfavorable cases showed a tendency to rise gradually toward the end of the disease, and excessively high readings were of bad omen unless they were associated with symptoms of cerebral edema. At the conclusion of such an attack the pressure dropped to its former level. Acute cerebral complications did not occur as often in chronic nephritis as in the acute postinfectious type, but they were just as amenable to treatment. The advent of such symptoms must not be confused with terminal uremia, true renal insufficiency. In the latter event no treatment is of use, whereas in the former, adequate administration of fluids and magnesium sulphate by mouth, muscle or vein is a life-saving procedure. Four of our patients had acute cerebral attacks of this type.

4 *Nonprotein Nitrogen Values of the Blood*—Some elevation of the figures for the nonprotein nitrogenous constituents of

the blood was often but not always found at the first observation, and this tended to fluctuate with the other symptoms. Late in the disease it rose, paralleling to a certain extent the course of the blood pressure. Many patients went on for years with approximately normal values, only to have them rise with a terminal insufficiency. The figures in children do not rise as high as they do in adults, however.

5 *Hematuria*—This was usually present to a marked degree early in the disease and, although gross hematuria rarely existed for a long period, it appeared

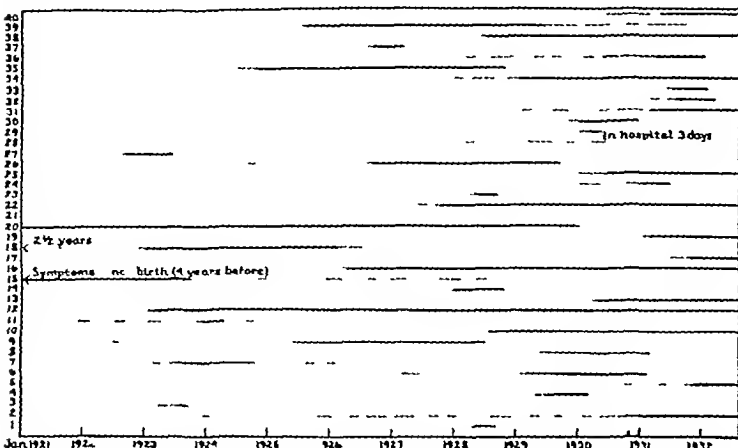

Chart 1—Duration of observation and duration of illness of all patients in this group. The broken line shows illness not supervised in this clinic. The heavy line shows illness while under observation. The beginning and end of each line shows the approximate onset and termination respectively.

antedate the infection. Six others described an ordinary cold or other questionable mild infection preceding the onset. One had a severe urticaria just before the onset. The remaining twenty-eight gave absolutely no history of acute antecedent infection of any kind. Headache, nausea and nocturia were frequent complaints. This type of onset contrasts sharply with that found in acute postinfectious hemorrhagic nephritis and makes us doubt the identity or chronological relationship of the two diseases. Careful history taking was necessary to bring out this point because, as might be expected, these patients were often first seen during acute exacerbations coincident with infectious processes. However, a careful check of the history usually revealed that symptoms of the nephritis preceded the acute infection. This point is of utmost importance in making a prognosis, because, if it can be definitely established that acute bacterial infection has preceded the first symptom of nephritis, one is justified in assuming a good prognosis and in excluding the patient from the classification of nonspecific nephritis.

2 *Edema*—Edema was usually found in the early stages but was often absent during the major portion of the illness (chart 3). All cases exhibited it at some time or other. The degree of edema varied considerably but usually was marked, resembling that seen in nephrosis. Moreover, as in nephrosis, the edema fluctuated for several months or a few years in some of the cases. We feel that the good response to salt free diets in this disease is an important differentiating point. In chronic nephritis salt restriction often controlled the edema fairly well, while in nephrosis we have never satisfied ourselves that it had therapeutic value. Many of our patients who seemed to require a salt free regimen over a few years finally became "dry," after which salt was well tolerated in large amounts. Even severe infectious processes have failed to produce

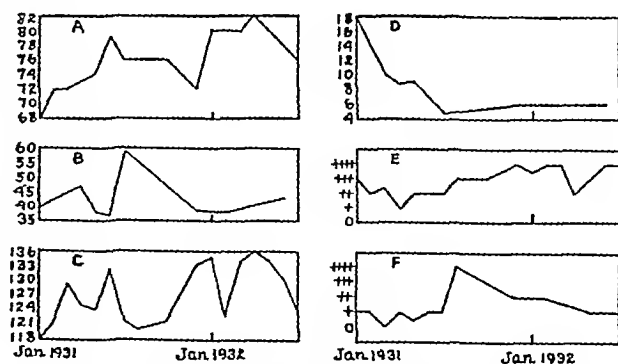

Chart 2—Fluctuation in various factors during the observation of one patient over a period of about eighteen months. A weight B nonprotein nitrogen C systolic blood pressure D Mosenthal variation E albuminuria F hematuria.

constantly in some. Such patients did poorly. On the other hand, hematuria was absent for prolonged periods in some patients even at the onset. This fact accounts for much confusion in diagnosis, especially in the differentiation from nephrosis. Careful history taking with hematuria in mind, prolonged observations, and the finding of other differentiating abnormalities such as hypertension and high blood nonprotein nitrogen values

will usually decide the question in a clear-cut manner. The fact that the hematuria is often transient, however, is responsible for many mistakes in diagnosis and prognosis.

6 Albuminuria—The amount of albumin was excessive, with rings 1 cm in thickness with Exton's reagent the rule rather than the exception. Great misunderstanding exists as to the constancy of this laboratory observation. Our experience with this group leads us to believe that the albuminuria is practically constant.

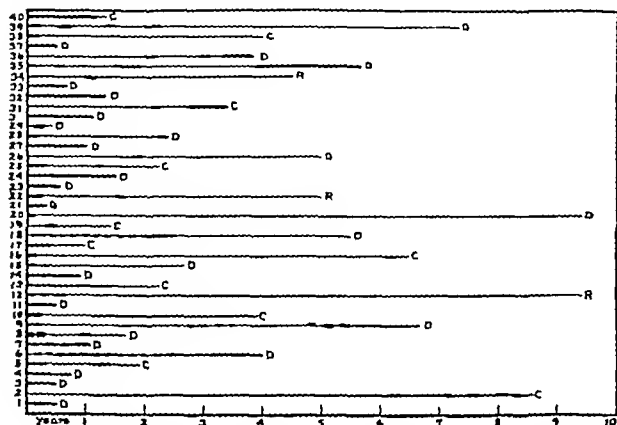

Chart 3—Incidence of edema in all the patients. The heavy parts of the lines represent periods in which the patient was edematous and the light parts represent periods during which edema was not present. It will be noted that edema was more common in the early stages of the disease than in the later periods. D death R recovery C chronic.

Records of patients who now have albuminuria show that, in a total of 1,479 reactions reported, only 26 were negative (0.18 per cent). The negative results have been so rare that we feel they may as well be ascribed to mistakes in technic or identity of the samples as to exceptions to the rule that the urine always shows albumin in this condition. The statement often made that the urine in chronic nephritis frequently clears up only to show a recurrence of albuminuria later must be challenged. Only two patients of the entire group showed positive albumin reactions following two or more consecutive negatives. Moreover, in our patients who have recently recovered, the albuminuria persisted long after all the other signs disappeared and, having once disappeared in such patients, did not return.

7 Cylindruria—Casts were always found in the early stages. They were a constant finding in all of our patients until recent changes in treatment were instituted. Since then we have seen patients in whose urine no casts have been demonstrable over many months, in spite of marked albuminuria.

8 Results of Renal Function Tests—In our work, because all patients were children, we used only the more easily applied tests. These included the two-hour specific gravity, water excretion and phenolsulphonphthalein tests. As might be expected, the water excretion test followed the course of edema rather closely. In most instances the variation of specific gravity became less than ten points soon after the onset. The variation increased somewhat with improvement in some of the patients, but a normal concentration response was relatively rare. The specific gravity tended to become lower and lower as the disease progressed. The phenolsulphonphthalein excretion was markedly diminished rather early in most cases, and,

surprisingly, some patients lived on for years with excretions of only 5 to 15 per cent of the dye.

9 Autopsy Results—Twenty-seven patients died. Twelve of these were examined post mortem. A complete discussion of the results cannot be attempted here, but two facts stand out in bold relief. First, the renal lesions were absolutely diffuse, no parts of the organs being spared in the degenerative and sclerosing processes. Second, at the time of death the patients were often grossly infected in various parts of the body, whereas until a relatively short time before death little clinical evidence of chronic microbic infection was demonstrable, as indicated in the accompanying table.

COMMENT

Critical consideration of the facts just outlined in the clinical picture and pathologic anatomy of this disease made us question some of the generally accepted theories as to its pathogenesis and influenced our management of the patients.

When we noted that only an occasional patient with chronic nonspecific nephritis gave a history of acute postinfectious nephritis at the onset and that even the patients most severely ill with postinfectious nephritis usually made complete and permanent recoveries, we began to doubt that we were dealing with identical processes. It seemed possible that the pathologic lesion in acute postinfectious hemorrhagic nephritis might be of a more benign nature than the progressive sclerosis found in chronic nonspecific nephritis. We began to think of chronic nephritis as a separate clinical entity and attempted, we think with considerable success, to differentiate it even in the early stages, before chronicity alone established its nature. This attitude made it necessary for us to look for some other cause than microbic infection, and, in casting about, we noted that almost all

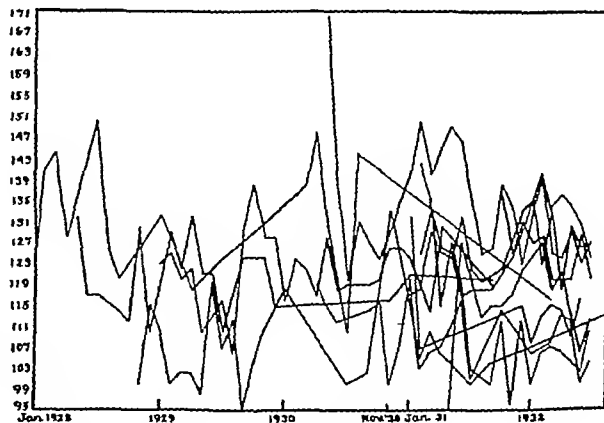

Chart 4—Fluctuations in systolic blood pressure over a period of four and a half years in the patients who were given the high protein high vitamin diet. It will be noted that there is no marked elevation in blood pressure following this change in November 1930.

cases were found in dispensaries, that the disease was a great clinical rarity among the well-to-do. Moreover, the patients were malnourished and surrounded by poor hygienic environment.

In the fall of 1930, having arrived at this stage in our observations, we were faced with a serious problem. The morale of the clinic was at a low ebb. All the patients with chronic nonspecific nephritis were receiving a low protein diet and many were forced to eliminate salt as well. Almost all were clinically ill and obviously dying off in spite of our good intentions.

They were a miserably ill, unhappy group of children. It was no pleasant duty to go on week after week and watch this process complete its degenerative course. Physicians, nurses, social service workers and patients had no heart in the job.

Therefore, in October, 1930, we resolved to make a radical change. All preconceived ideas of diet were discarded and we decided to treat these children exactly as we would any other group in as poor a nutritional state and to make every effort to improve their nutrition and their physical and mental hygiene. The following

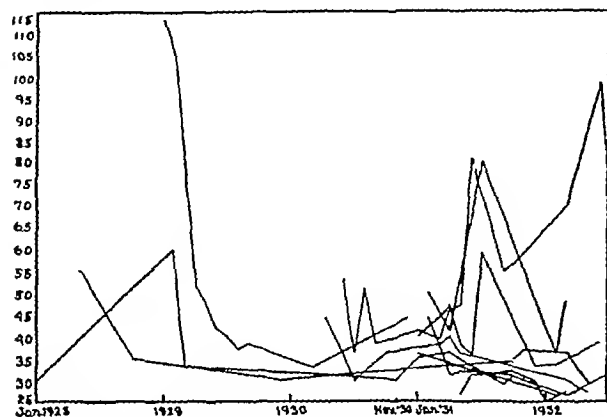

Chart 5—Fluctuations in nonprotein nitrogen in the patients given the high protein, high vitamin diet. It will be noted that in only one instance is there an elevation after the change in diet.

reasons were responsible for the decision. 1. The disease manifested some of the evidences of a nutritional, hygienic or deficiency disease. 2. Our previous treatment had been futile, if not actually harmful. 3. We hoped to make the remaining months or years of the patients' lives more endurable by giving them the satisfaction of eating palatable food just as did other folk.

The following measures were taken. All patients were put on a diet which we hoped might compensate for any deficiency. Meat or eggs were ordered three times daily, salt was allowed to all those who were not definitely edematous, and all the vitamins we had ever heard of were included in their diet. Cod liver oil, yeast, orange juice, and raw and cooked vegetables were prescribed. Wherever this could not be accomplished at home, we invoked the help of charitable organizations or took the patients into the hospital. In addition to this, every effort was made to improve the general hygienic environment of the children, including sun baths in the summer, fresh air, and the like.

While this was undertaken with some slight misgivings on account of precedent, we did not feel too guilty on account of the ten years of experience we had had on the regimen prescribed by precedent. The results following the change were so rapidly noticeable, however, that within three months doubt changed to surprise. All the patients began to look better. One returned with specimens of urine that were and have since been, constantly free from albumin. Since that time two more have become albumin free, a pleasure we had never before experienced. One by one the children became able to reenter school. Hemoglobin estimations rose along with the weight curves, and this without edema. Clinical improvement in general health was noted within a few weeks.

With still greater satisfaction, we found that in general neither the blood pressure (chart 4) nor the blood

nonprotein nitrogen values (chart 5) rose with this change.²⁰ In fact, the tendency was toward a decline in many instances. While the albuminuria has continued in most children, it tended to decrease in amount and disappeared entirely in three instances. The red blood cells have disappeared in eleven of fourteen living patients and casts are now a relatively rare observation among them.

Of the ten patients put on this regimen in October, 1930, only two have died. While apparently improving, they left our care and were put on low protein, salt free diets in other institutions. One patient died under such treatment, and the other returned to us in a moribund condition to die in acidosis of true uremia.

We have now under observation in the dispensary thirteen patients, twelve of whom have been receiving this diet for over two years. All are attending school regularly. With one exception, all are in an excellent nutritional state, and the weight, hemoglobin and tissue turgor are good (chart 6). The one child who is not in good condition was in desperate shape before the new regimen was instituted but has been able to resume school work in spite of his severe nephritis. He is the only patient in this group who shows a progressive loss of renal function.

As a result of two years' experience with this dietary and hygienic regimen, we can report that the majority of our patients have shown definite clinical improvement, that three have shown complete disappearance of clinical evidence of the disease, that one is continuing the downward course at a retarded rate, and that the death rate has been decidedly reduced.

SUMMARY

A brief description of the clinical features exhibited by forty children with chronic nonspecific nephritis is

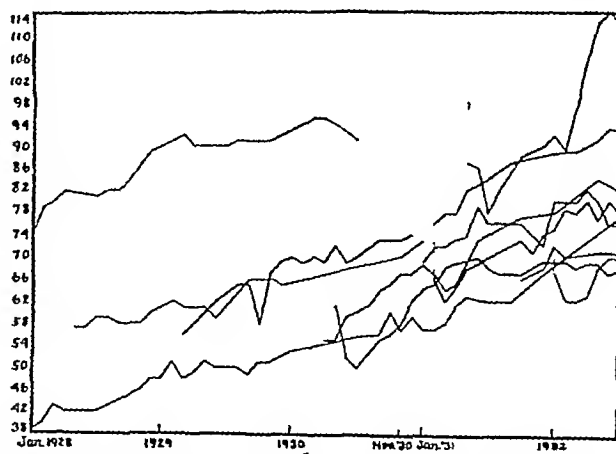

Chart 6—Weight increment in these patients over a period of four and a half years. The vertical broken lines show the initial loss of weight due to edema.

given, including the results of treatment over ten years with low protein diets.

After the institution of high protein, high vitamin diets and improved hygienic care, definite clinical improvements were seen.

This high protein diet did not cause elevation of the blood pressure or increase the nonprotein nitrogenous constituents of the blood in the group as a whole.

²⁰ Recent observations on one patient in the stage of terminal renal insufficiency seem to show that when the nitrogenous retention is marked added protein may increase the nonprotein nitrogen of the blood. This was not the case in the instances with moderate retention.

It is suggested that this type of chronic nephritis is due to some hygienic or dietary cause rather than to microbic invasion and that infection may be the result of the disease rather than its cause

We are describing a children's disease, we do not know that this identical condition exists in adult life

PURPURA HAEMORRHAGICA IN CONGENITAL SYPHILIS FOLLOWING ARSPHENAMINE

REPORT OF TWO CASES

J. V. BICKFORD, M.D.

AND

R. C. TILGHMAN, M.D.

BALTIMORE

Studies of the toxic effects of the arsphenamine derivatives have received a prominent place in the literature as the extent of the usage of these drugs has increased in the treatment of syphilis. To the list of untoward reactions caused by them have been added the blood dyscrasias. That a selective injury of one of the elements of the hematopoietic system may be caused by the arsphenamine preparations is shown by the reports of (1) cases of granulocytopenia, in which there results a suppression of the granulocytic series, or (2) of cases of purpura haemorrhagica in which a thrombocytopenia is the conspicuous feature, or (3) of cases of aplastic anemia in which there is a generalized depression of all types of blood formation. The severity of the blood disorder is variable, in some there is complete recovery with restoration to a normal blood picture, in others the outcome is fatal. Fortunately, blood dyscrasias resulting from antisyphilitic treatment with the arsphenamines are infrequently encountered.

Analytic studies in two papers of recent date have dealt with the reported cases of postarsphenamine blood dyscrasias. Loveman,¹ in April, 1932, including Farley's series,² reviewed sixty-four cases with thirty-one deaths, or a mortality of 48 per cent. Thirty of his patients had aplastic anemia, of whom eighteen died, a mortality of 60 per cent, fourteen had purpura haemorrhagica with five deaths, or 36 per cent mortality, and fifteen were examples of granulocytopenia with six deaths, or 40 per cent mortality. In thirty-five of these patients neoarsphenamine was the drug employed with seventeen deaths, arsphenamine in ten patients with five deaths, sulpharsphenamine in six with three deaths, silver arsphenamine in two with one death, and mixed arsphenamine therapy in eight with four deaths, arsphenamine preparations were used but the kinds were not stated in three patients with one death.

McCarthy and Wilson³ in November, 1932, were able to collect from the literature seventy-nine cases of arsphenamine poisoning, including many of those reported by Loveman. Sixty-five of these were classi-

fied as follows: 1. Thrombocytopenic purpura, twelve cases, in all of which recovery occurred, in seven of these cases neoarsphenamine was the last drug used and in the remaining five cases sulpharsphenamine was the last drug used. 2. Associated thrombocytopenia and granulocytopenia, seven cases, in one of which death occurred, in five of these cases (including the fatal one) neoarsphenamine was used, in one sulpharsphenamine and in one silver arsphenamine. 3. Granulocytopenia, twelve cases with four fatalities, or 33 per cent mortality, arsphenamine was the drug used in four cases, neoarsphenamine in five, sulpharsphenamine in one, and both neoarsphenamine and sulpharsphenamine in two. 4. Aplastic anemia, thirty-one definite and three probable cases with six recoveries, or a mortality of 83 per cent, in this group arsphenamine was used in twenty-two cases, sulpharsphenamine in five, both neoarsphenamine and sulpharsphenamine in one, and arsphenamine in four, in two cases the arsphenamine preparation was not specified. McCarthy and Wilson take care to point out that while the bulk of the blame for the toxic reactions has been placed on neoarsphenamine, this drug has been more generally used than others of the arsphenamine series. Relative to the total use of sulpharsphenamine, blood dyscrasias from this preparation are surprisingly frequent.

Our purpose in this paper is to report two cases of purpura haemorrhagica in children with congenital syphilis following the use of neoarsphenamine. These are the only examples of postarsphenamine blood dyscrasias of any kind occurring in the syphilis clinic of the Harriet Lane Home for Invalid Children of the Johns Hopkins Hospital. The records show that 1,825 children have been treated for syphilis in the Harriet Lane Home and a total of 25,950 treatments given from October, 1922, to January, 1933. Though no figures are available of the exact number of children who have received arsphenamine, nearly every child treated for syphilis receives arsphenamine at some time during the course of antisyphilitic treatment. It is apparent, therefore, that the incidence of postarsphenamine blood dyscrasias in children is extremely low.

PROTOCOLS

CASE 1—A. R., a white boy, aged 6 years, was admitted to the hospital March 1, 1932, shortly after an antisyphilitic treatment, with the diagnosis of a severe reaction to neoarsphenamine.

The boy was first seen in the outpatient department in August, 1927, four and a half years before (at the age of 1½ years). He was sent in to have a Wassermann test, which proved to be positive. It was learned at this time that both parents were syphilitic, the father had previously received antisyphilitic therapy and the mother died in October, 1927, of paralysis from syphilis, the exact nature of which could not be determined from the records. There was no family history of miscarriages or stillbirths.

The physical examination of the patient at the time when first seen was reported as not showing any of the stigmas of congenital syphilis. There was no general glandular enlargement and the liver and spleen were not felt. A second observer, three weeks after the first examination, noted slight general glandular enlargement and a palpable liver and spleen.

The first antisyphilitic therapy was started Sept. 13, 1927. The child was given 0.19 Gm. of sulpharsphenamine. For a year and a half he received fairly regularly weekly treatments of sulpharsphenamine and the Wassermann reaction remained positive. Owing to irregularity in reporting for the injections, many of the six weeks courses were incomplete. In the history during the first course of treatment, "trouble with his bowels" was noted. Another later report reads "sick and vomits when ever he does not get his treatment. An infantile reaction."

From the Harriet Lane Home, Johns Hopkins Hospital and the Department of Pediatrics, Johns Hopkins University (Dr. Bickford) and from the Department of Medicine, Johns Hopkins Hospital (Dr. Tilghman).

2. Farley, D. L. Depressed Bone Marrow Function from Arsphenamines Including Type of So-Called Agranulocytosis. *Am. J. M. Sc.* 179: 214 (Feb.) 1930.

3. McCarthy, F. P. and Wilson, Robert Jr. The Blood Dyscrasias Following the Arsphenamines. *J. A. M. A.* 88: 1557 (Nov. 5) 1932.

After the third injection of the seventh course of sulpharsphenamine, a note in the history reads 'does not know condition of the child after last treatment.'

Following the next treatment, the fourth in the seventh course, a purpuric rash and nose bleeding were recorded. The patient was not brought to the dispensary until eleven days afterward (March 23, 1929). Physical examination at that time showed an enlarged lobulated liver extending 4 cm below the costal margin, spleen not palpable, several large black and blue spots evidently from traumas and a fading purpuric rash. Laboratory data included a bleeding time of ten minutes, platelets markedly reduced, and a leukocytosis with a relative lymphocytosis, estimated from a blood smear.

From April 9, 1929, until June 16, 1931, over a period of twenty-seven months, the boy received bismuth instead of arsenical compounds as an antisyphilitic therapy. In June, 1931 he was given one dose of neoarsphenamine without any reaction. Between June, 1931 and February, 1932 he did not receive treatments but on the latter date a regular course of neoarsphenamine was started. The first dose, of 0.15 Gm, did not give a reaction, the second dose, of 0.24 Gm, also was without any untoward reaction. The third dose was increased to the calculated amount for the patient's age, and 0.31 Gm of neoarsphenamine was given. Immediately on leaving the treatment room after this injection, the child began to vomit. In a few minutes he was cyanotic, the pulse was of poor quality. The child was at once admitted to the hospital. In a word, the appearance and the physical examination were characteristic of those encountered in shock.

Treatment in the ward consisted of morphine and epinephrine followed by intravenous administration of dextrose. The child responded well, the cyanosis improved and the

3 hours	66 mg per hundred cubic centimeters

general condition became better. By evening (nine hours later) the child seemed so well that it was expected he would be discharged the following morning.

The following morning, however, it was discovered that a purpura had developed during the night. There were ecchymotic discolorations about the site of the intravenous and hypodermic injections. Bleeding was occurring from the nose and gums. There were numerous small petechiae over the pharynx and palate, some over the chest and tibias. A submucous hemorrhage about 2 cm in diameter was present in the buccal cavity. The liver was palpable 4 cm below the costal margin. The spleen was not felt. There was no jaundice present. Laboratory examination revealed red blood cells 4,700,000, hemoglobin 86 per cent, white blood cells 7,800, with a differential count of 63 per cent polymorphonuclears and 32 per cent lymphocytes. No abnormal cells were seen in the stained smear. The platelets were so few that a count by the direct method was worthless, by the indirect method the platelet count was 68,000. Unfortunately, determinations of bleeding and clotting time were not done at this time. The patient was given two small transfusions of 120 cc of citrated whole blood, after the second of which the bleeding stopped. The urine at no time showed any blood. It contained a trace of albumin on admission but none on subsequent examinations. The stool was faintly positive to the guaiac test on the third day after admission, probably because of swallowed blood from hemorrhages in the mouth. The blood pressure was 98 systolic, 60 diastolic, and the temperature remained normal throughout the entire hospital stay. The number of white blood cells increased from day to day until at the time of discharge the count was 12,500. The differential count remained normal throughout. Even at the time of discharge, five days after the reaction, the blood smear was practically devoid of platelets. A van den Bergh test done on the third day after the illness gave an indirect reaction. Since the question of liver damage was considered, a

levulose tolerance test was performed on the third day after the reaction with normal results.

At the time of discharge, on the sixth day, the child appeared well. The petechial spots and hemorrhagic discolorations were still present but were fading. The liver remained 4 cm below the costal margin, and the tip of the spleen was just palpable.

On examination three weeks after discharge, the child appeared healthy. The liver edge was at the costal margin, and the tip of the spleen could still be felt. There were no evidences of the purpuric eruption. Laboratory data at this time included a bleeding time of three and one-half minutes, clotting time, three minutes, red blood cells 4,620,000, hemoglobin 86 per cent, white blood cells, 9,170, with a normal differential count of 61 per cent polymorphonuclears and 31 per cent lymphocytes. A blood smear was still practically lacking in platelets, only two small clumps of platelets being seen in an entire blood film.

The patient was not given any further antisyphilitic treatment. Examination in November, 1932, seven months after the purpuric reaction showed that the child was normal except for chronic tonsillitis and a positive Wassermann reaction. No stigmas of congenital syphilis were observed. The child was allowed to continue on probation.

The child was last seen, Feb. 11, 1933, approximately one year after the reaction to arsenical therapy. Laboratory examination gave normal results. The bleeding time was two and one-half minutes, the clotting time, three minutes (the clot retracted normally). The total white blood cell count was 7,200, the differential count polymorphonuclears 45 per cent, lymphocytes, 45 per cent, monocytes, 10 per cent. The smear showed platelets in normal numbers and no abnormalities.

CASE 2—E. B., a well developed white boy, aged 8 years, was admitted to the hospital, Feb. 5, 1929, with the complaint of bleeding from the gums, easy bruising and a rash after an illness of two weeks, commencing abruptly following an intravenous injection of 0.375 Gm of neoarsphenamine.

The mother was infected with syphilis by her first husband seven years before the birth of the patient and she was treated at the time and pronounced cured. Later she divorced the husband and married the man who became the father of the patient. The first pregnancy resulted in an uninfected child. The second pregnancy, by the second husband, resulted in another uninfected child. The third pregnancy resulted in the birth of the patient.

The child had snuffles in infancy and hydrarthrosis at the age of 5 years. At this time both the mother and the child were discovered by their private physician to have positive Wassermann tests. The child was treated by the physician for two years (between the ages of 5 and 7 years) and was given repeated courses of intravenous therapy. Notwithstanding this, he developed a bilateral interstitial keratitis and was brought to this institution July 24, 1928, in the fourth month of the keratitis. At that time a suggestively positive blood Wassermann reaction was reported but the spinal fluid Wassermann reaction was negative. The first treatment at the Harriet Lane Home was given July 31, 1928, and the blood Wassermann reaction was reported negative August 8. There had never been any unfavorable reaction to previous arsenical treatment. The keratitis healed well.

In all, the child had received two full six weeks' courses of neoarsphenamine in the doses of 0.33 Gm each and at the beginning of the third course the dose was increased to 0.375 Gm (the patient weighing 56 pounds, or 25 Kg, at the time). About an hour after the third injection in this course he began to bleed freely from the mouth. In a few hours after the treatment he was covered with petechial spots. About thirty-six hours after the injection he bumped himself against a box, a very trivial injury, and a huge effusion of blood into the gluteal muscles occurred. By this time he was covered with small purpuric spots pretty much over the entire body. There were no constitutional symptoms. The bleeding time was eleven minutes, the clotting time seven minutes. A stained blood smear showed a leukopenia with a relative agranulocytosis. No platelets were seen in the smear. On the following day the stools became tarry, but the child had swallowed much blood from the mouth bleeding.

For the few days intervening between these episodes and the time of admission to the hospital little new was noted. The child did not seem unwell and there was no frank bleeding. The condition remained stationary, with occasional outcropping of petechiae.

On the morning of admission, eleven days after the injection, which seemed to start the bleeding and the beginning of symptoms, the mother took the child to the dental department, where two teeth were extracted. Bleeding followed, and the child was brought immediately to the hospital.

On physical examination the child was not in acute distress. No stigmas of congenital syphilis were discovered. Scattered everywhere over the body, with the sole exception of the scalp and face there was a petechial eruption (less marked on the back), which did not blanch on pressure. The color of the petechiae varied from a fairly bright red to a dirty brown. There were numerous larger purpuric patches looking quite like bruises scattered here and there over the body varying in size from 0.5 to 1.5 cm. Two striking purpuric areas were present, one roughly, 8 by 5 cm in the left antecubital fossa and the other occupying the greater part of the left buttock. Neither of these patches was tender. The buttock felt firm but evidently was not infected. The mucous membranes of the eyes showed some petechiae. The buccal mucosa was covered with a film of fresh blood and also many small petechiae and larger patches. There was no general glandular enlargement and the epitrochlear lymph nodes were not palpable. The pupils were slightly dilated and reacted sluggishly to light. Except for a refractive error the eyes were normal. Examination showed the heart and lungs to be normal. There were no masses or tenderness in the abdomen. The liver was

Blood Sugar Determinations in Case 2

Fasting	108 mg	per hundred cubic centimeters
½ hour	139 mg	per hundred cubic centimeters
1 hour	127 mg	per hundred cubic centimeters
1½ hours	115 mg	per hundred cubic centimeters
2 hours	110 mg	per hundred cubic centimeters

felt and percussed about 1.5 cm below the costal margin on the right and 1 cm in the midline. The spleen, palpable 2.5 cm below the costal margin, seemed firm, easily movable and rather elongated. The kidneys were not felt. The joints were freely movable without enlargement, tenderness or increased heat. The reflexes were normal.

Laboratory examination at the time of admission disclosed red blood cells, 4,290,000, hemoglobin, 80 per cent with color index of 1.0, white blood cells, 7,000, with a normal differential count of 67 per cent polymorphonuclears and 31 per cent lymphocytes. The blood smears showed that the red cells stained well without central achromia, anisocytosis or poikilocytosis. The platelets were markedly diminished, the platelet count being 180,000. The bleeding time (filter paper method) was five minutes, the clotting time (capillary tube method), ten minutes (normal, six minutes). Examination of the urine was negative except for a strongly positive urobilin. A tuberculin test of 0.1 mg was negative.

The patient remained in the hospital for eight days. He was afebrile on admission and remained so during his stay. The oral bleeding stopped within thirty-six hours and did not recommence. Since there were no further purpuric manifestations, transfusion seemed unnecessary. On the sixth day after admission the hemoglobin was still 80 per cent, bleeding time twenty minutes and clotting time ten minutes, platelet count, 150,000. On the day of discharge (the eighth day after admission) the bleeding time was ten minutes.

There has been much discussion as to the possibility of liver damage. The enlargement of the liver and the presence of urobilin in the urine on admission was regarded as suggestive of liver injury. However, it seemed more probable that the urobilin could be attributed to the absorption of the ecchymoses, of which the one on the buttock was very large. A van den Bergh test was not done because of the possibility of extravasation following venipuncture. A test of liver function was performed on the day of discharge. Levulose, 1 Gm per kilogram, was given by mouth.

The blood sugar determinations showed a normal curve and provided nothing on which to base suspicion of liver damage. Dye tests were not done, because it was feared that any such procedure might cause another purpuric attack.

The child was seen one week after leaving the hospital. He had had no further purpuric manifestations. A blood smear at the time showed some anisocytosis and poikilocytosis, granulocytes that appeared normal, and a normal number of platelets.

No more antisyphilitic treatments were given until two months after the purpuric attack at which time treatment with a bismuth compound was started, and continued until three full six weeks courses had been given. At the end of that time, treatment was considered complete.

Since October, 1929, until the present time, February, 1933, Wassermann examinations repeated every six months have continued negative. The last examination, Feb. 14, 1933 showed a normal child with no stigmas of congenital syphilis and a negative Wassermann reaction. Laboratory examinations gave normal results. The bleeding time was two minutes, clotting time, three and one-half minutes (test tube method), clot retraction, normal. A differential count showed polymorphonuclears, 53 per cent, eosinophils, 1 per cent, lymphocytes 41 per cent, monocytes, 5 per cent. Smears contained abundant numbers of platelets, white blood cells, 8,000.

COMMENT

In both of our cases, no familial tendencies to bleeding could be discovered and no hemorrhagic tendencies in the patients themselves had ever been observed. In case 1 the reaction was immediate and severe with the manifestations of circulatory collapse. In case 2 the reaction was more prolonged and more gradual in onset and less severe. In case 1 there had been a previous mild reaction three years earlier, which in retrospect may be taken to indicate a sensitivity to the drug. Patient 2 exhibited nothing to indicate drug or chemical sensitivity. The blood pictures were similar in the two cases and the clinical pictures with petechiae and ecchymoses, involving both skin and mucous membrane, were also similar. In both cases, complete recovery occurred. The treatment of patient 1 was in the main that of shock, e. g., warmth, epinephrine, morphine, intravenous dextrose, and blood transfusions to combat further bleeding. In case 2, treatment was unnecessary and the recovery was entirely spontaneous. Needless to say, arsenicals of any kind are to be avoided in further antisyphilitic treatment of these patients.

The mechanism by which abnormal blood pictures are produced by injections of the arsphenamine derivatives is not clearly understood. Bedson⁴ reported that experimentally an extensive, though temporary, reduction in the number of platelets in the circulatory blood did not give rise to purpura and presented evidence to show that the main factors concerned were (a) a toxic action on the endothelium of the vessels and (b) the removal of the platelets from the circulation.

There are a number of workers who attribute the disturbance in hematopoietic function directly to the toxic effects on the bone marrow of the benzene and arsenic components of the arsphenamines, and the prevailing opinion is that the benzene radical is the more responsible of the two. Jui-Wu-Mu⁵ reported an immediate reduction of platelets in from ten to thirty minutes in normal individuals after the first injection of neoarsphenamine, but in none of his patients did a hemorrhagic state develop. Other observers believe that an allergic factor may play a part, their evidence

⁴ Bedson, S. P. Blood Platelet Antiserum Its Specificity and Role in the Experimental Production of Purpura, *J. Path. & Bact.* 26: 94 (Jan.) 1922.
⁵ Jui-Wu-Mu. Effects of Neoarsphenamine on the Number of Blood Platelets. *Proc. Soc. Exper. Biol. & Med.* 26: 407 (March) 1929.

seems to lie in the fact that in the reported cases the blood dyscrasia has developed only after repeated injections of the arsphenamines. If a "specific sensitivity" phenomenon is involved, it differs from that ordinarily observed in arsphenamine dermatitis in that a gradually cumulative process of "sensitivity" must be postulated. In order to bridge the obvious gaps in the mechanism, Loveman and others assume a "syphilitic" factor. One can only raise the question why the phenomenon should occur so rarely in cases of florid syphilis, if a toxic element of the syphilitic infection itself is responsible.

No conclusive evidence seems available at present to decide the etiology of postarsphenamine blood dyscrasias in syphilitic patients. Our purpose here is to add two cases to the literature, so that eventually sufficient data may be studied to aid in the final solution of the problem.

CLINICAL EVALUATION OF THE GALACTOSE TOLERANCE TEST

BENJAMIN M. BANKS, M.D.

PERCY H. SPRAGUE, M.D.
Fellow in Medicine the Mayo Foundation

AND

ALBERT M. SNELL, M.D.
ROCHESTER, MINN.

Since the introduction by Bauer¹ in 1906 of the galactose test as a method of determining hepatic function, there has been considerable difference of opinion among competent observers as to its practical value. The metabolism of this sugar has been studied intensively, both in this country and abroad, but its application to clinical material received only scanty consideration here until the appearance of the contribution of Shay, Schloss and Bell.² These authors have given an excellent review of the literature and have outlined the clinical application of the test. They have pointed out the many advantages of galactose as a test substance: (1) its availability in pure form, with freedom from associated gastro-intestinal upsets following its administration, (2) its prompt assimilation from the alimentary canal unchanged and its conversion into glycogen in the liver, (3) the apparent inability of the remainder of the organism to utilize or store galactose as such, and (4) its lack of a renal threshold characteristic.

As is generally known, clinical application of the test is based on the fact that the normal fasting person, after ingestion of 40 Gm. of galactose, will utilize nearly all of this amount and excrete up to a total of 3 Gm. in the urine in five hours. It has been thought that an output exceeding this arbitrary limit of 3 Gm. (a positive test) indicates diffuse parenchymal hepatic injury such as seen in "intrahepatic" jaundice. In obstructive jaundice it has been felt that the hepatic parenchyma retains its ability to metabolize galactose, and if this is true, excretion of less than 3 Gm. (a negative test) should prevail in the presence of this condition. Basing their argument on these assumptions,

Shay and Schloss² concluded that the galactose test "is a simple, ready means of identifying a clinically difficult group of cases, namely, the toxic or infectious jaundice group, and of separating it from the obstructive type." This view has recently been restated by Bauer,⁴ the originator of the test; in addition, he has expressed the belief that the galactose tolerance test furnishes a more or less direct measurement of the severity of hepatic injury. During the last eighteen months this test has been used at the Mayo Clinic as a routine in various types of jaundice in patients who were hospitalized. This affords an opportunity to evaluate its diagnostic accuracy.

In reporting our results we have selected those cases of obstructive jaundice in which diagnosis has been confirmed by operation, necropsy, or both. Of cases of intrahepatic jaundice we have included only those in which the patients gave definite histories of taking hepatotoxic drugs or in which the clinical picture of epidemic or catarrhal jaundice was present. In addition, the clinical course in these last mentioned cases, as well as follow-up studies for six months made the clinical diagnosis reasonably certain. Among the patients with metastatic hepatic malignant conditions, three who later died elsewhere are included, in these cases the diagnosis was obvious, as was evidenced by a palpable, nodular liver and rectal implants. A group of persons who were not jaundiced but who had miscellaneous diseases of the biliary tract and liver and who had been subjected to the bromsulphalein test of hepatic function was also investigated by this method. This selected group of cases numbered 127 in all and our experience with these cases forms the basis of this communication.

The technic of the test followed in this study is essentially identical with that outlined by Shay and Schloss. After an overnight fast the patient empties his bladder, this specimen being saved as a control. He then drinks a solution of 40 Gm. of galactose in 500 cc. of water flavored with a few drops of lemon juice. Thereafter the patient may drink water freely. Specimens of urine from the resting patient are collected hourly during the next five hours, and each is placed in a separate container appropriately labeled. At the conclusion of the five hours, each specimen is tested with the Benedict qualitative reagent for reducing substances. Those samples which give positive tests are mixed, and the total reducing substance is determined by the quantitative method of Benedict. The results are expressed as grams of total reducing substance. The same two trained technicians have performed all the tests. Specimens of urine of diabetic patients have been checked by standard fermentation methods to rule out glycosuria.

INTRAHEPATIC JAUNDICE (TOXIC OR INFECTIOUS)

Acute and Subacute Types—The eighteen patients who comprise this group (table 1) are of particular interest in view of the difficulty and necessity of accurate differential diagnosis between the condition they represent and painless obstructive jaundice, especially that caused by obstruction of the bile ducts by malignant processes. That age is an unreliable guide to diagnosis is shown by the fact that a third of this

group of patients were more than 50 years of age. With the exception of only three cases, excretion of galactose on at least one occasion during the period of hospitalization was 3 Gm or more. In some of these cases repeated determinations were made and interesting variations in galactose tolerance were observed, as shown in the chart. Shav and his co-workers have

posed on the more chronic one. Our observations in this group agree in a general way with those recently published by Bauer.

OBSTRUCTIVE JAUNDICE

Carcinoma of Pancreas and Bile Ducts, Metastatic Carcinoma of Liver—Of twenty proved cases of carcinoma of the head of the pancreas or ampulla of Vater, with jaundice ranging in duration from three days to six months, there were nine in which galactose tests were positive (table 3). There was no constant relationship between the duration and depth of the jaundice and the amount of galactose excreted, nor could the test be regarded as of great prognostic significance. It is a remarkable fact that in case 55 as the patient approached the stage of terminal hepatic insufficiency, with increased drowsiness, purpura, and rising values for serum bilirubin and blood urea, the tolerance for galactose improved, so that the successive tests disclosed decrease in excretion of galactose from 4.60 to 2.18 Gm.

In the ten cases of primary neoplasm of the common or hepatic ducts (table 3), the jaundice was fairly acute, averaging two weeks in duration. Five patients in this group gave positive tests on at least one occasion. Again, no prognostic significance could be attached to the results of the test. Patients 40 and 48, who presented positive galactose tests, died from postoperative hepatic insufficiency, as did patients 41 and 47, who had previously had normal tolerance for galactose.

Variations in galactose tolerance and value for serum bilirubin in a case of intrahepatic jaundice

also noted a rise and fall in total galactose output, corresponding apparently to progression and recession of the disease. During the early stages of certain mild cases a negative test may be present, and on repetition the excretion of reducing substances may never rise above the arbitrary upper normal limit of 3 Gm.

Case 18 (table 1), in which there was jaundice of three months' duration following sulpharsphenamine, obviously must be included in this group as an example of subacute hepatic parenchymal injury. Excretion of galactose of 1.3 Gm is a reflection of extensive hepatic regeneration during that period, as evidenced also by the marked decline to normal limits in value for serum bilirubin while the patient was under observation.

It is clear from examination of table 1 that in acute and subacute intrahepatic jaundice the test, although usually reliable, is not infallible. However, its value as additional evidence when correlated with the usual clinical and laboratory observations is exemplified by case 10, in which a diagnosis of obstructive jaundice had been made. Operation was postponed when the galactose tolerance test was reported as positive, with excretion of 6.36 Gm of reducing substances in the urine. The jaundice subsided gradually thereafter, the patient's general condition improved, and on reexamination six months later he was found to be in excellent health.

Chronic Types—In contrast to the preceding series the patients now to be considered, who for the most part had various types of portal and biliary cirrhosis, had consistently normal galactose tolerance, with excretion usually between 2 and 3 Gm (table 2). From the histories and physical examinations it is apparent that the underlying processes of hepatic destruction and repair had been active for many months before jaundice actually supervened, and the presence of newly regenerated hepatic tissue may thus explain the normal utilization of galactose by these patients. It is noteworthy that in two instances (cases 20 and 22) increased excretion of galactose fell to normal values as the patients recovered from brief episodes of jaundice. Transient increases of bilirubinemia in this type of case obviously suggest an acute process superim-

We have included with our cases of obstructive jaundice resulting from a malignant condition a group of seven patients with metastatic malignant deposits in the liver. It is appreciated that under these conditions jaundice may not necessarily be obstructive, however, the not infrequent absence of jaundice in advanced

carcinomatosis of the liver as seen at necropsy suggests that the usual mechanism of jaundice under these conditions is a blocking of intrahepatic or external biliary ducts by metastatic nodules or involved lymph nodes. Three of these seven patients excreted galactose in excess of 3 Gm. This is contrary to Bauer's experience, he has recently stated that a metastatic malignant condition of the liver rarely produces any significant change in galactose tolerance. This statement probably applied to nonjaundiced patients with such a condition, but in cases of proved metastatic malignancy and jaundice positive galactose tests are not uncommon in our experience.

In a total, therefore, of thirty-seven proved cases of jaundice secondary to malignant disease, obstructing the bile passages or metastasizing to the liver, or both, positive galactose tests were obtained in seventeen (46 per cent).

Cholelithiasis, Cholecystitis with Stones and Associated Hepatic Lesions. Stricture of the Common or Hepatic Ducts—There were twenty-two cases of obstructive jaundice caused by stone in the common

the common or hepatic ducts at operation (table 4), although the patients were jaundiced at the time. All of these patients were found, however, to have serious degrees of hepatitis or cholangitis. In three cases excretion of galactose was normal, of the two patients who presented positive tests, one (85) was described as having an atrophic and cirrhotic liver and the other (87) was found to have a maximal degree of hepatitis and cholangitis. The former patient made a good recovery after operation, but the latter died with symptoms of hepatic insufficiency and hemorrhage. The three patients with negative galactose tests had uneventful convalescence, in spite of the undoubted presence of hepatic cellular injury.

In cases of stricture of the common or hepatic ducts the antecedent history of chronic disease of the biliary tract, and the tendency of the biliary obstruction to be of long standing, persistent, and practically complete, would predicate the existence of a more advanced form of parenchymal hepatic injury than that which usually follows other types of mechanical occlusion of the bile passages. In eleven cases in which plastic

TABLE 2—Chronic Intrahepatic Jaundice

Case	Age Years	Sex	Diagnosis	Duration of Jaundice	Serum Bilirubin*	Galactose Tolerance†	Comment
19	49	♂	Cirrhosis with ascites and jaundice	1 week	6.3 to 10.7	2.85	Marked alcoholism; ascites for three months prior to admission; rising serum bilirubin curve
20	35	♂	Alcoholic cirrhosis with jaundice	1 week	5.6 to 1.5	3.12 4.84 2.08	Extreme alcoholism; liver greatly enlarged; fluctuating serum bilirubin curve
21	30	♂	Splenohepatic disease, Banti's syndrome (?)	10 days	12.6 to 1.6	2.01	Marked alcoholism; fluctuating serum bilirubin curve; splenectomy; liver moderately en- larged and cirrhotic; surface diffusely nodular
22	51	♂	Cirrhosis with ascites and jaundice	2 weeks	16.7 to 4.8	3.10 1.80	Marked ascites for one month prior to admis- sion; falling serum bilirubin curve
23	45	♂	Cirrhosis with ascites and jaundice	2 months	5.4 to 2.9	2.37	Marked alcoholism; enlarged liver and spleen; ascites
24	24	♂	Biliary cirrhosis with splenomegaly	3 months	8.3 to 7.1	2.27	Moderate ascites and collateral circulation; report of death two months later
25	60	♂	Cirrhosis with ascites and jaundice	6 months	5.2 to 3.3	2.85	Ascites six months prior to admission
26	16	♂	Portal cirrhosis	6 months	3.6 to 2.4	2.00	Blood including fragility of erythrocytes normal
27	20	♂	Biliary cirrhosis with splenomegaly	5½ months	7.1 to 6.5	2.18	Markedly enlarged liver and spleen
28	51	♀	Cirrhosis with ascites and jaundice	9 months	3.9 to 10.0	2.74	Ascites two months prior to admission; fluctu- ating serum bilirubin curve; Talma Morrison operation done
29	40	♀	Infectious biliary cirrhosis	14 months	4.3 to 5.8	2.52	Operation at onset of jaundice; diagnosis made and T tube inserted in common bile duct
30	54	♂	Cirrhosis with ascites and jaundice	16 months	8.8 to 6.3	2.00	
31	51	♀	Biliary cirrhosis with splenomegaly	24 months	6.8 to 6.0	2.80	Hepatic biopsy seven years previously at operation for chronic cholecystitis disclosed biliary cirrhosis

† Grams excreted in urine in five hours.

bile duct (table 4). In each case, notes made at operation or necropsy, concerning the color of the bile and the appearance and condition of the liver, were available. In six cases in which jaundice was present from ten days to many months, excretion of galactose exceeded 3 Gm. No apparent correlation existed between the degree of hepatic injury noted by the surgeon and the total excretion of galactose, nor could one prophesy from the results of the tests either the type of postoperative convalescence or the probability of fatal outcome. Thus, three patients (64, 67 and 71) with negative tests had definite postoperative hepatic insufficiency, and one died, of the six patients with positive tests, only one failed to survive operation. Postoperative hemorrhage occurred with approximately equal frequency in cases with positive and in cases with negative tests.

There were five cases of cholecystitis with stones in which calculous material could not be demonstrated in

repair for stricture of the common or hepatic ducts was carried out (table 4), moderate to extreme degrees of biliary cirrhosis and cholangitis were actually present, in all, at operation or necropsy. Four of these eleven patients gave positive galactose tests. Two of the four patients had uneventful convalescence, whereas the remaining two failed to survive.

It is noteworthy that both in cases 93 and 94, despite negative galactose tolerance tests, "white bile" was found at operation. The postoperative course was characterized by signs of hepatic insufficiency in both cases and by marked hemorrhagic tendency in one.

A remarkable example of residual obstructive biliary cirrhosis secondary to stricture of the common bile duct was observed in one case (99). A strongly positive galactose test (15 Gm excreted in five hours) was obtained shortly before death. At necropsy the terminal picture of hepatic insufficiency was presented with jaundice, ascites, and gastro-intestinal hemorrhage.

Extensive cirrhotic changes were noted in the liver, with nodular hyperplasia and a marked degree of fibrosis, the pathologic picture, in fact, closely resembled that of advanced alcoholic cirrhosis

Our experience with the galactose test in the thirty-eight cases (table 4) of jaundice due to choledocholithiasis, stricture, and cholecystitis with hepatitis and cholangitis may be summarized by the statement that positive tests were obtained in a third of the cases. This percentage is not significantly altered by excluding

PATIENTS WITHOUT JAUNDICE

Our experience with the test on normal control subjects coincides with the results of numerous investigators and confirms the upper limit of excretion of galactose under the conditions of the test as 3 Gm. Numerous tables appear in the literature rendering inclusion of our own data on this point unnecessary. The contention of Rowe⁵ that galactose tolerance, as determined by his own experimental technic, varies with sex apparently does not affect the uniform clinical application of the test to jaundiced patients of both sexes.

In a miscellaneous group of twenty-one cases of disease of the biliary tract and liver, the results of the galactose test were compared with the bromsulphalein test of hepatic function. Not one of these patients was jaundiced at the time either test was performed. The dye test gave positive results in fifteen cases, but in only two cases was the galactose test positive and in

these the deviation from normal was slight. In several cases of this group, extensive hepatic lesions were noted at operation or at necropsy, and in these the bromsulphalein test was uniformly positive, although excretion of galactose was within normal limits. In one case the hepatic substance was almost entirely replaced by a bile duct type of primary hepatic carcinoma, retention of dye was graded 4, whereas excretion of galactose was normal, 1.62 Gm. It is apparent from these cases that a determination of galactose tolerance may be of little, if any, clinical value in hepatic disease not associated with jaundice.

COMMENT

In considering the applicability of the galactose test to clinical material, it is worth while to review some of the more recent experimental evidence on the subject. Bollman, Power and Mann⁶ have shown that only 80 per cent of galactose may be recovered from the urine of the hepatectomized animal after intravenous injection. Also, if the equivalent dosage of this sugar is given orally to hepatectomized dogs, there is somewhat greater loss, which may be due to oxidation in the muscular tissues of the animal. This phenomenon may be explained on the basis of relatively slow absorption of galactose from the digestive tract. These workers also showed that there were marked variations in the absorption and excretion of galactose in normal dogs and in those with experimental cirrhosis. They concluded, however, that galactose is theoretically the sugar of choice for the testing of carbohydrate metabolism in hepatic disease.

Certain inherent pitfalls in conducting the clinical tests make a rigorous technic necessary. Vomiting and diarrhea are obvious causes of faulty absorption, but gastric stasis, whether functional from reflex causes, or mechanical, as in malignant conditions of the upper part of the digestive tract, is a less obvious cause of malabsorption. In aspiration of gastric content performed at the end of the five-hour period it was by no means rare to recover considerable amounts of the test sugar, thus invalidating to some extent the test in question. The delay in absorption secondary to the retarded circulation present in certain types of chronic hepatic disease may also be of some significance. In addition to defective absorption, faulty excretion of the sugar due to renal and vesical factors may introduce appreciable errors. Oliguria, whether caused by dehydration or by acute renal injury associated with the primary hepatic disease, will result in an unreliable low output of galactose. Functional retention of urine in the bladder, and residual urine in the presence of a hypertrophied prostate gland may also mask a positive test.

Various metabolic factors, at present still controversial and confusing, may serve in a nonspecific way to vitiate the test. Particularly in dehydration and starvation, as well as in febrile conditions, the results should be interpreted with caution. Standards of normal presuppose an adequate carbohydrate reserve. The studies of Shay, Schloss and Bell and of Roe and Schwartzman⁷ tend to indicate that excretion of galactose in the urine of diabetic patients is comparable with that of normal persons, however, the latter investigators noted in dealing with diabetic patients an average increase

in fermentable (dextrose) blood sugar of 40 mg in each 100 cc during the period of the test. In view of the general knowledge as "summation of effects of glycosuric tendencies," it is advisable to perform fer-

glycosuria or actual diabetes, patients with thyrotoxic states may well be included in the group of cases in which galactose tests are to be interpreted with particular care.

TABLE 4—Nonmalignant Obstructive Jaundice

Case	Age Year*	Sex	Diagnosis*	Duration of Jaundice	Serum Bilirubin†	Galactose Tolerance‡	Comment
02	37	♀	Stone in common bile duct hepatitis choolangitis pancreatitis	4 days	10.7 to 7.1	1.07	Stormy postoperative convalescence

mentation tests on the urine of all patients with frank diabetes or with diabetic dextrose tolerance curves, regardless of whether the fasting subject has glycosuria or not. Readings of the fasting blood sugar and dextrose tolerance tests may also be indicated in exceptional cases. Because of their tendency to alimentary

In a considerable number of the cases studied, intravenous injections of a 10 per cent solution of dextrose were given daily as a preparation for surgical treatment. The question has been raised as to whether one or many such injections would vitiate a galactose tolerance test done on a subsequent day. It has been repeatedly noted

(Allen⁸ and Folin and Berglund⁹) that the utilization of any sugar is modified when another assimilable sugar is given simultaneously by the same or a different route. This objection does not hold in this instance, however, since the injections of dextrose were completed at least twenty hours before the galactose was administered. On hypothetical grounds it would seem that previous, or even simultaneous, administration of dextrose should increase the hepatic glycogen and improve hepatic function, thus serving to reduce the excretion of galactose. The experiments of Bloch and Weisz¹⁰ appear to substantiate this view, and those of Corley¹¹ are not contradictory. In experimental animals with obstructive jaundice, Millet¹² also has shown that repeated preliminary injections of dextrose may increase the galactose tolerance rather than decrease it. On this basis it would seem that a previous injection of dextrose such as many of our patients received, would at least not tend to increase the number of positive tests but, if anything, would reduce their number.

The value of a test of hepatic function to both internist and surgeon is directly proportional to its accuracy in establishing or supporting a clinical diagnosis, in indicating, in medical cases, improvement or lack of it, in determining in cases under consideration for operation the degree of risk, and in predicting probable postoperative complication. Judged by these exacting standards, the merits of the galactose test may be questioned, indeed, it is doubtful whether any single test will ever fulfil these requirements.

In cases of acute intrahepatic jaundice of average severity, a positive galactose test is almost the rule. A negative test may occur in the presence of nonobstructive jaundice either in mild or convalescent cases, or in cases of long standing, and does not necessarily militate against the diagnosis. However, positive tests occur with considerable frequency in the presence of obstructive jaundice of various types (from 32 to 46 per cent of all types in this series). As will be noted from the tables, most of these positive tests involve excretion of galactose of from 3 to 4 Gm. A more strongly positive test (excretion of 6 Gm or more of reducing substance) is more likely to indicate an intrahepatic type of jaundice and should be a serious deterrent against immediate surgical intervention. Either the condition is entirely intrahepatic, that is, not surgical, or preoperative treatment should be instituted to reduce the risk incidental to possible associated parenchymal hepatic injury.

In following the clinical course of patients with intrahepatic jaundice, the test undoubtedly has some definite prognostic value, especially when the value for serum bilirubin has become "fixed" and varies but little from day to day. Millet's studies on galactose tolerance of animals with experimental hepatic injury produced with carbon tetrachloride, diaminitoluene, or tetrachloroethane are in agreement with the foregoing observations. In his experience, acute, severe hepatic injury usually produces increased excretion of galactose, milder degrees of injury produce no appreciable change,

in the presence of chronic hepatic injury, the response to administration of galactose is variable. The presence of active hepatic regeneration apparently leads to negative tests, both under experimental conditions and in clinical cases even though the preceding hepatic injury has been extensive.

As we have stated, in the presence of obstructive jaundice, tests were positive in our series in from 46 (malignant) to 32 per cent (benign) of the cases. The tendency for the obstruction in cases of malignancy to be complete and persistent probably accounts for the higher percentage of positive tests in the malignant group, but the part played by biliary infection and biliary cirrhosis in cases of stone and stricture is probably not inconsiderable in affecting the excretion of galactose. The reasons for these deviations are apparent from pathologic studies. Counseller and McIndoe¹³ have demonstrated the marked degree of hydrohepatosis, infection of the larger bile passages and biliary parietal sacculi and of injury to the hepatic parenchyma secondary to biliary obstruction or to interference with portal circulation. In nine of the nine cases of obstructive jaundice which came to necropsy the galactose test was positive, and there was apparently a sufficient amount of hepatic injury to explain the results. In the other cases, less extensive parenchymal injury was noted.

It is recognized that not infrequently in the liver a condition of degenerative change or actual atrophy may develop following obstruction to the outflow of bile, in such cases the galactose test would seem fully as likely to give a positive result as in pure types of intrahepatic jaundice. In other cases of obstruction the processes of regeneration and repair may follow closely in the wake of hepatic cellular destruction, and a negative galactose test may belie the extent of hepatic disorganization. In short, there are definite anatomic reasons why a galactose test may be misleading in the presence of obstructive jaundice, and it is no serious criticism of the test to say that its range of error in this condition may be considerable.

From a physiologic standpoint, studies on the character and composition of bile following surgical relief of biliary obstruction of long standing¹⁴ further illustrate the functional inadequacy of the liver which may follow occlusions of the bile passages. As Millet has shown in the experimental animal, the excretion of galactose following ligation of the common bile duct varies considerably in different animals and in the same animal at different times. The individual tolerance to biliary obstruction varies widely both in the experimental and in the human subject, and the amount of hepatic parenchymal injury secondary to obstruction may likewise be extremely variable. No doubt these variations explain, to some extent at least, the inconstant results of galactose tolerance tests. As with all other functional studies applied to the liver, perfection is hardly to be expected, clinical data furnish a basis for diagnosis, laboratory data being chiefly of corroborative value. The galactose test may be of great assistance in deciding matters of diagnosis and treatment in certain cases, but in our opinion the possibility of considerable margin of error should be considered in the interpretation and clinical application of the test in

every case, particularly if clinical data and the result of the test do not agree

CONCLUSIONS

We feel that the galactose test does not uniformly distinguish between obstructive and toxic or infectious types of jaundice, although it may furnish valuable corroborative data in doubtful cases. In both intra-hepatic and obstructive types of jaundice strongly positive tests (excretion of 6 Gm or more) should be seriously regarded and, if excretion is consistently high, are probably indicative of serious injury to the hepatic structure. The borderline group of positive tests with excretion of only slightly more than 3 Gm of reducing substance, should not be regarded as conclusive evidence against the presence of mechanical biliary obstruction. The value of the test to the individual practitioner will depend on how carefully its results are weighed against time-honored clinical data and previous clinical experience with jaundiced patients.

WEAKNESS AND FAILURE OF THE LEFT VENTRICLE WITHOUT FAILURE OF THE RIGHT VENTRICLE

CLINICAL RECOGNITION

PAUL D WHITE, MD

BOSTON

In the practice of medicine today no more important condition is encountered or so often unrecognized as such as is weakness or congestive failure of the left ventricle without congestive failure of the right ventricle. I propose herewith to discuss as a definite clinical syndrome or entity features of left ventricular failure in man which permit its recognition and which demand appropriate treatment.

My interest in this condition has been aroused in the past ten years by the observation of frequent instances of congestive heart failure, by special studies of my own¹ by the writings of certain others, and by the astonishing fact that so little attention has been paid by the English speaking world either in practice or in writing to this state of congestive failure of the left ventricle without congestive failure of the right ventricle. There has been this neglect not only by the medical profession at large but also by many cardiologists and even by some of the leaders. Realization of the truth has been slowly penetrating my own mind largely as the result of the study of three conditions that have interested me because of their relative neglect in English literature. These conditions are (1) cardiac asthma^{2a} (2) protodiastolic gallop rhythm^{1c} and (3) pulsus alternans^{1b}. To complete the clinical evidence of left ventricular weakness and failure that is available today one should add to the three features named four others which are also very important in the presence of heart strain (in particular, hypertension, coronary thrombosis, and aortic valvular disease) limited to the left ventricle. These four features are (4) cardiac dyspnea without engorgement of the systemic veins (5) diminished vital capacity without extracardiac

cause, (6) increase in the roentgen shadows of the lung hilus blood vessels, and (7) increasing accentuation of the pulmonary second sound. The four conditions just mentioned are also found with mitral stenosis and of course that lesion must be ruled out before these conditions in any given case can be considered as clear evidence of left ventricular failure.

THE LITERATURE

The history of the study of left ventricular failure is a fascinating one. I have traced the concept back more than 100 years.

In the earliest books on the heart itself, beginning two centuries ago, there gradually grew up over a period of 100 years the definite conception of enlargement of the heart from strain of some sort. In 1728 Lancisi² wrote on aneurysm or enlargement both of the heart and of the arteries. Incidentally he described a new sign, namely engorgement and pulsation in the cervical veins due to transmission of pressure upward from a dilated right heart.

DeSenac,³ in 1749 wrote of cases of cardiac enlargement with and without valvular disease and related asthma to some kinds of heart disease, he described among others a case of aortic stenosis with cardiac asthma and secondary dilatation of the right heart. Morgagni,⁴ in 1760, continued the discussion of heart strain and resulting enlargement and cited several cases. In 1806 Corvisart discussed active and passive aneurysm of the heart, signifying hypertrophy and dilatation as active aneurysm and dilatation alone as passive aneurysm. Bertin⁶ in 1811, introduced the terms concentric hypertrophy and eccentric hypertrophy to denote simple hypertrophy of a ventricle and hypertrophy with dilatation, respectively. But it was Hope⁷ of Edinburgh and London who, so far as I have been able to find out, was the first clearly to point out that the left ventricle may weaken under some strain with resulting congestion of the lungs and secondary strain thereafter on the right ventricle. Hope also was the first clearly to describe cardiac asthma. His writings in 1832 are so vivid and so much to the point on these important conditions that I shall quote briefly from them now.

As an obstacle to the circulation operates on the heart in a retrograde direction the cavity situated immediately behind it is the first to suffer from its influence. Accordingly all the impediments seated in the aorta its mouth, or the arterial system, act primarily on the left ventricle which, being likewise exposed to the heaviest burden when the circulation is accelerated has to conflict against a greater variety of exciting causes of hypertrophy, than any other cavity of the heart. On this account therefore, as well as from the thickness of its parietes, it is subject to hypertrophy in a greater degree than any other.

So long as the left ventricle is capable of propelling its contents the corresponding auricle, being protected by its valve remains secure. Hence in a large majority of cases the auricle is perfectly exempt from disease while the ventricle is even enormously thickened and dilated. But when the distending pressure of the blood preponderates over the power of the ventricle, its contents from not being duly expelled constitute an obstacle to the transmission of the auricular blood. Hence the auricle becomes overdistended, and the obstruction may be prop

agated backward through the lungs to the right side of the heart and there occasion the same series of phenomena. When the obstruction thus becomes universal, as is frequently the case it may either happen that all the cavities are thickened or those only which from their conformation have the greatest predisposition to it.

The primary effect of universal obstruction of the lungs by engorgement is to produce edema of their cellular tissue and dyspnea whether the latter depends solely on the engorgement or partly also on spasm of the bronchi excited by the irritation of that congestion is difficult positively to determine though the latter is highly probable.

Asthma has been too much regarded as independent of disease of the heart. Long treatises have even been written upon it without ever mentioning disease of this organ as one of its causes. It is therefore, necessary to dwell a little on this subject not only for the purpose of showing the magnitude of the error, but of making the reader acquainted with all the habitudes and aspects of a complaint which is perhaps the most distressing in the whole catalogue of human maladies.

Asthma from disease of the heart often imitates the character of the other varieties and this perhaps for a very simple reason that the lungs are in much the same state as in those varieties. Thus, it is *humid* when there is permanent engorgement of the lungs, causing copious seromucous effusion into the air vessels, as from contraction of the mitral valve. It is *dry* when the engorgement is only temporary as in cases of pure hypertrophy. It is *continued* when there is a permanent obstruction to the circulation and any of the varieties may be *convulsive* when the heart has sufficient power to palpitate violently. The worst cases of convulsive asthma from disease of the heart are those of hypertrophy with dilatation and a valvular or aortic obstruction.

I apprehend that whatever be the organic cause of asthma it requires for its production the superaddition of a state of the nervous system leading to spasmodic constriction of the bronchial tubes. In what this state consists we can no more say than why one female falls into hysteria and another does not on seeing a third laboring under that affection or why one lady 'dies of a rose in aromatic pain' while another prefers it to all other perfumes.

Mind you this was all written 101 years ago. If only I had read older medical works of this high standard earlier and more diligently I should have been spared much pondering and should have realized that we have been gradually rediscovering some old ideas about left ventricular strain and about the probable mechanism of cardiac asthma though on sounder foundation of course than it was once possible to build. It is astonishing that with the passage of time Hope's teachings were neglected. Already within thirty years of Hope's book one finds that Stokes⁸ has hardly a word to say on these points and after him right up to the present day most of the foremost English works on the heart in succession are strangely silent on this very important subject. There is usually in these books ample discussion of increased pressure and congestion of the systemic veins in heart failure but little or nothing about a similar state of congestion of the veins in the lungs due to failure of the left ventricle which is an early and common and often amenable functional disturbance at least as important (and probably more important) to recognize as is failure of the whole heart or of the right ventricle alone. Dyspnea is universally acknowledged to be a common early symptom of heart failure or usually stated to be the first evidence of such failure even before there is any sign of increased pressure in the systemic veins but its true significance and its pathogenesis are too often passed by and cardiac asthma, though mentioned, receives scant discussion.

However, there have been in the present generation here and there, a few English writings that recognize left ventricular failure without right ventricular failure and I shall quote briefly from three. Hirschfelder,⁹ in 1918, wrote

Shortness of breath is usually the earliest and most common sign of cardiac failure and especially of failure of the left ventricle. Cough, dyspnea, cardiac asthma, pulmonary hemorrhage constitute a group of symptoms characteristic of stasis in the pulmonary veins (broken pulmonary compensation) just as cyanosis, enlargement of the liver, and ascending edema are characteristic of failure of the right heart. In Wilkinson King's "safety-valve action of the right ventricle," failure of the latter substitutes a state of broken systemic compensation for one of broken pulmonary compensation.

G. Canby Robinson,¹⁰ who stimulated his school at Nashville to pursue the study of heart failure wrote in 1927 as follows:

In our study of patients we are able to distinguish cases in which the left side of the heart is inefficient relative to the right side of the heart, from those in which the right side of the heart is relatively inefficient. While this distinction cannot be made with certainty in all cases some cases show a disturbance in the pulmonary circulation out of all proportion to the disturbances in the systemic circulation. These cases are suffering we believe from relative failure of the left ventricle which is unable to handle properly the blood sent to it by the right ventricle. Other cases show edema of the extremities and congestion of the abdominal viscera while the pulmonary circulation shows no evidence of being disturbed. In such cases the right ventricle is relatively inefficient, and is unable to receive and propel all the blood sent to it by the left ventricle. In many cases the disturbance of coordination between the ventricles affects both the greater and lesser circulations so that both show evidence of heart failure.

Sonia Weiss¹¹ in 1931, wrote that 'in early stages of circulatory failure changes occur in the pulmonary circulation' that changes in the pulmonary circulation may be independent of the larger circulation that one does find early [in heart failure] a reduction of the vital capacity of the lungs" and that "dyspnea in the early stage of circulatory failure is produced through nervous communications between the pulmonary system and the medulla and not by local chemical changes within the respiratory center." Weiss and his associates have continued an active interest in heart failure and have published other more recent papers on the subjects of cardiac asthma¹² the state of the peripheral and pulmonary circulation in various types of heart failure¹³ and the effect of digitalis¹⁴. Their work will be eventually assembled in detail and will include roentgenologic observations by Dr. Robb¹⁵.

On turning to the French and German literature one finds clear recognition of the syndrome of left ventricular failure in the writings of the present day and back over a period of fifty years or more. In 1889 for example Fraentzel¹⁶ attributed pulmonary edema to

acute distention of the left ventricle, in his lectures he wrote "We observe frequently cases of edema of the lungs if the right ventricle still works with its normal strength while the left flags in its work" Fraentzel was also one of the first to emphasize the clinical significance of the important type of gallop rhythm as a sign of serious cardiac weakness, although Potain,¹⁷ Traube¹⁸ and Barie¹⁹ had all referred to it earlier and recognized its importance. A present-day French authority, Lian,²⁰ has emphasized the clinical significance of the syndrome of left ventricular insufficiency, distinguishing between paroxysmal and continuous and between mild and severe types. He wrote in 1910 that "breathlessness on effort, palpitation left ventricular dilatation gallop rhythm passive pulmonary congestion reveal above all a left ventricular insufficiency which is but little pronounced and has developed

hearts in which some factor of strain is evident (and in most hearts such factors are obvious both in their presence and in their influence) the left ventricle is under a burden much more often than is the right. The total of essential hypertension, coronary thrombosis, and aortic valve lesions is far greater in the community than is that of mitral stenosis pulmonary valve stenosis and pulmonary disease sufficiently extensive to act as a strain on the heart.

Among the last 100 patients of mine who showed heart failure by evidence either in the pulmonary or in the systemic circulation or in both and in whom etiologic factors were clear, 74 per cent showed primary left ventricular strain, 14 per cent showed primary right ventricular strain and 12 per cent showed strain on both ventricles (table 1). Over the period of time during which these 100 cases consecutively occurred

100	Grand total			400					

The percentages refer to the 376 cases with definite factors of strain

slowly. In these cases generally the failure of the left heart induces that of the right heart." Cardiac asthma he recognized as evidence of acute left ventricular insufficiency.

This brief historical survey will suffice to show the vicissitudes of the conception of left ventricular failure and to point to its common neglect in medical practice and writings of the English speaking world of the present day.

THE FREQUENCY OF LEFT VENTRICULAR FAILURE

A brief analysis of cases of congestive heart failure reveals at once the preponderant frequency of failure of the left ventricle with or without failure of the right ventricle which so often follows. The majority of

there were 16 other cases that presented congestive failure without clearly recognizable factors. Also there were in the same time interval 284 cases of organic heart disease without evidence of congestive failure, among 276 of these in which etiologic factors were clear strain was preponderantly on the left ventricle in 183, or 66.3 per cent, preponderantly on the right ventricle in 46, or 16.7 per cent and on both ventricles in 47, or 17.0 per cent (table 1).

Thus, among 400 consecutive cases of organic heart disease the left ventricle was under the greatest strain in 64.3 per cent, the right ventricle in 15 per cent, both ventricles in 14.7 per cent, and in 6 per cent the type or primary location of the strain was not clear.

These cases, which I have studied personally in the past two years illustrate the point already emphasized that congestive failure of the left ventricle is more common and important than that of the right and should be looked for zealously since by early recognition and proper treatment not only may the left heart failure

17 Potain. Du rythme cardiaque appelé bruit de galop. Union med 1875 quoted by Fraentzel¹⁴ p. 59.

20 Lian. C. Le syndrome d'insuffisance ventriculaire gauche. Presse med 18 49 1910.

be relieved but the right heart failure which is likely to follow, may be prevented or postponed.

As a control study of these cases of my own seen in private practice I have analyzed the last 100 cases of congestive heart failure with clear factors of strain seen in the general medical wards of the Massachusetts General Hospital expecting a somewhat higher incidence of rheumatic heart disease with mitral stenosis than in my private practice. This survey (table 1) gave the following results: primary left ventricular strain sixty-one cases, or 61 per cent (systemic hypertension twenty, coronary disease or thrombosis, seventeen, both systemic hypertension and coronary disease, eighteen, aortic stenosis or regurgitation or both without mitral valve disease and with or without hypertension six), primary right ventricular strain, nineteen cases, or 19 per cent (mitral stenosis sixteen, extensive pulmonary disease three), and strain on both ventricles twenty cases or 20 per cent (aortic and mitral valve disease fifteen, thyrotoxicosis three, mitral stenosis aortic regurgitation and coronary occlusion, one, mitral stenosis and systemic hypertension one).

In passing, it may further be pointed out that only about one in four of the cases of organic heart disease that I have seen in consultation has shown evidence of heart failure or insufficiency. This is especially significant, since my patients are at least as severely affected as those seen in general practice in the community at large. The point I would raise here is that the central interest of the practitioner of medicine should not, as some have asserted, be in the cases of failure, which of course he should recognize and treat properly, but rather in the cases without failure that have more promise for the future and that need recognition much more than do the more advanced cases, advice and treatment for these should help to prevent or at least to postpone the onset of heart failure.

SYMPTOMS AND SIGNS OF LEFT VENTRICULAR FAILURE (WITH OR WITHOUT RIGHT VENTRICULAR FAILURE)

I shall now take up briefly the symptoms and signs by which one may recognize left ventricular failure (with or without right ventricular failure). All of them are not necessarily present in the same case any more than is all the classic evidence present at one time in a case of subacute bacterial endocarditis but their assemblage under one heading which has not been completely carried out before so far as I know, will, I am sure, be helpful.

1 *Dyspnea of Cardiac Origin Without Mitral Valve Disease or Congenital Defects*—This kind of shortness of breath has always rightly been emphasized as evidence of cardiac weakness and often recognized as occurring before any evident increase of pressure in the systemic veins. Whatever its nervous mechanism may be and no matter how it is excited, its fundamental cause is almost certainly an increase in pressure in the pulmonary circulation with engorgement of the blood vessels. Resulting from this engorgement of the vessels there are two immediate effects—an encroachment on the air spaces of the alveoli and a stiffening of the alveoli to cause a state of functional emphysema. That this is so can be deduced from the other signs that I shall discuss shortly, namely decrease of vital capacity, visible engorgement of the blood vessels of the lungs on roentgen examination, and accentuation of the second heart sound in the pulmonary valve area. The

failure of many authorities to visualize engorgement of the pulmonary vessels resulting from failure of the left ventricle is of course due to the fact that they have been hidden from view for so long and that engorgement of the systemic veins, so readily seen, follows often very quickly after left ventricular failure and attracts undue attention. In my own cases in which it was possible to estimate the time interval between left ventricular failure and right, as best known in instances of paroxysmal dyspnea, the results varied greatly from a few hours to months or even years. As an illustration of a long time interval, I would cite the instance of a physician who has been under my observation for the past five years with pulsus alternans and protodiastolic gallop rhythm almost constantly and dyspnea on effort or paroxysmally at night (much benefited by digitalis), who went for nearly five years before he showed any increased venous pressure behind the right ventricle, when it did appear, it was in the liver largely and was dispelled by rest and digitalis.

2 *Cardiac Asthma or Acute Pulmonary Edema*—This is an extremely important clinical condition, evidence as a rule of acute failure of the left ventricle but open to an amazing amount of controversy in the past. Some there are who evidently have never seen a case of cardiac asthma and who therefore doubt its existence, but those of us who have seen a number of patients with this most distressing condition, usually in the middle of the night, can doubt neither its existence nor its significance. One of the important points about it is that it may come sometimes without previous warning that is with little or no dyspnea previously. About half of the patients with cardiac asthma whom I have seen recently have had such an experience. Almost invariably there is serious heart disease involving the left ventricle in patients with cardiac asthma—hypertensive enlargement, infarction from coronary thrombosis, or aortic valve disease with stenosis, regurgitation or both. There are a few exceptions. Of the twenty-seven patients with cardiac asthma or acute pulmonary edema whom I have encountered in private practice in the past two years, twenty-four had heart disease involving the left ventricle, as previously noted and three had mitral stenosis, this last small group is an interesting significant and much neglected one—it is most probable that in them the cardiac asthma is precipitated by pulmonary vascular congestion not the result of acute failure of the left ventricle but rather the result of the tachycardia and overactivity of the right ventricle (generally from overexertion) in the face of marked mitral stenosis. Dr. Sylvester McGinn and I are about to report a group of cases of this nature.

Among my series of 100 recent cases of congestive heart failure, cardiac asthma or acute pulmonary edema occurred twenty-four times, in thirteen cases without any evidence of engorgement of the systemic veins and in eleven cases with such systemic venous engorgement occurring later on or coincidentally. I would add that in my experience, although acute pulmonary edema may occur without asthmatic breathing, such an occurrence is rare, somewhat comparable perhaps to the infrequency with which one encounters cases of acute coronary thrombosis without pain.

3 *Vital Capacity of the Lungs*—A few individuals have followed the important lead of Peabody²¹ and his

²¹ Peabody, F. W. and Wentworth, J. A. Clinical Studies of the Respiration. IV. The Vital Capacity of the Lungs and Its Relation to Dyspnea, Arch. Int. Med. 20: 443 (Oct.) 1917.

associates and of Pratt²² in emphasizing the value of spirometric measurements in estimating the degree of pulmonary congestion in cardiac failure. Most of us have tended to scorn such a test on the score that it is not sensitive enough and that it is too subject to influence by all sorts of factors besides heart failure. However, from recent experience, as evidenced in an example to be recounted later, I would advise the resumption of this test in selected cases, particularly in those cases of left ventricular strain in which a control base line has been established either before failure has occurred or after it has been dispelled. Used with judgment the vital capacity may be as satisfactory a gauge of pulmonary vascular engorgement as is measurement of the systemic venous pressure instrumentally or by inspection of the neck veins. West's²³ standards of 2.5 liters of vital capacity per square meter of body surface for men and 2 liters for women are suitable as average normal figures for comparison.

4 Roentgen Evidence of Pulmonary Vascular Congestion.—With the advent of roentgen study, it became possible to see the pulmonary artery and great veins and their branches, and in 1920 Assmann²⁴ suggested measurements of the shadows of the lung hilus to determine increases under abnormal conditions. Assmann found that the normal width of the shadow of the lung hilus was from 12 to 13 mm (more easily measured on the right side). Of twenty patients studied by him with a hilus shadow width of over 15 mm, nineteen had organic heart disease, some with failure of the left ventricle. Dietlen²⁵ and a few others followed Assmann's example but except to make general statements about the hilus shadows and lung markings in heart disease, little has been done in careful study of this relationship. Holmes,²⁶ in 1923, reported the increase of lung markings in heart disease as a condition that should be differentiated from pulmonary disease. Recent experience, as in the case to be reported, has caused me to believe that here one may have a useful, perhaps even a quantitative, method for the determination of the degree of pulmonary congestion in left ventricular failure. Of course, in mitral stenosis and congenital heart disease and in pulmonary disease the hilus shadows may be large, too, but of these conditions I am not now speaking. With Dr Holmes and Dr McGinn I am making further studies. In the case cited later, the area of the hilus shadows decreased one half in two weeks with improvement under digitalis therapy.²⁷

5 Pulsus Alternans.—I come finally to three additional signs of weakness or failure of the left ventricle, the first one, alternation of the pulse, is practically the only pathognomonic sign known of such weakness. It is a common sign, if one includes, as one should, pulsus alternans following premature contractions for a few beats. Only the most marked grades can be picked up by palpation of the arterial pulse, and of course such a condition must not be confused with bigeminal heart rhythm. Moderate grades of alternation can be

picked up by sphygmomanometry but the slightest grades satisfactorily only by sphygmography. All grades are important, but it is open to question whether one should go to the trouble of hunting for the slightest grades by mechanical pulse tracings. If this is done, slight grades can often be found, as I found some years ago.^{1b} Probably it suffices to study carefully the pulse coming under the blood pressure cuff at the systolic pressure level. The finding of pulsus alternans is most common with heart weakness in heart disease due to hypertension, coronary disease, or aortic valve disease. I noted the presence of definite pulsus alternans of 2 or 3 up to 10 or 15 mm of mercury in 8 of the 100 cases with heart failure that are tabulated. Among these eight patients four had hypertensive heart disease, two coronary thrombosis, and two the combination of hypertension and coronary thrombosis. All but one patient had also protodiastolic gallop rhythm. Four of the eight have died within this interval of two years. Most certainly, had I searched more diligently I would have found more cases among the other ninety-two.

6 Protodiastolic Gallop Rhythm.—A loud third sound occurring shortly after the second and heard best at the cardiac apex, in the absence of mitral stenosis and of auriculoventricular block, is one of the most valuable and neglected signs known of weakness and probably of dilatation of the left ventricle. Most English textbooks are astonishingly silent about this sign, which I find to be extremely helpful in confirming a diagnosis of left ventricular weakness. It is often attended by a palpable impulse. When the heart rate is fast, the sound and impulse fall in the middle of diastole or even at the end of it, but when the rate is slower its protodiastolic timing is more evident. It may even occur when the auricles are fibrillating. This sign was present in 32 of the 100 cases of my series outlined, being confined almost entirely (30 cases) to those patients with preponderant left ventricular strain, in the remaining 2 cases it was found with severe anemia and with failure in acute rheumatism in childhood. Among the 30 patients with preponderant left ventricular strain, 10 had a history of chronic hypertension, 6 of coronary thrombosis, 10 of both hypertension and coronary thrombosis while 4 had aortic valve disease, 3 with regurgitation and 1 with stenosis. Ten of the patients had had cardiac asthma. Of the 32 patients, 13 died within two years of the finding of the gallop rhythm.

7 Increase in Intensity of the Pulmonary Second Sound.—This is often a helpful confirmatory sign of increased pressure in the pulmonary circulation, especially in cases of essential hypertension in which with the onset of failure of the left ventricle the accentuation of the aortic second sound gives way to that of the pulmonary second sound with restoration of the original condition when the failure is cleared.

Murmurs are of little or no importance in cases of failure of the left ventricle. They may or may not be present. The commonest murmur when one is found is a systolic blow at the apex, probably denoting relative mitral insufficiency. Weakness of the apical first sound is occasionally but not constantly found. Auricular fibrillation may be found with failure of the left ventricle, but it has been my experience that this is usually not the case, it is common knowledge that it is much more frequent in cases of mitral stenosis. In my own series of 100 cases of congestive failure presented in table 1, it occurred twenty-one times, in ten of the

27 Definite roentgen evidence of actual edema of the lungs themselves may be found in cases of high grade congestive failure, it is not an early sign. When there is emphysematous or asthmatic breathing due to congestive failure the diaphragmatic excursions may be much limited with the diaphragm at a low level as in bronchial asthma.

eleven cases of mitral stenosis in three cases of hypertension, in five cases of coronary disease, and in three cases of hypertension and coronary disease combined. Tachycardia of normal (sino-auricular) origin is quite common in congestive failure of the left ventricle, tending to disappear when there is relief by digitalis therapy or rest. Paroxysmal tachycardia may precipitate failure of a heart with little reserve.

IMPORTANCE OF THE RECOGNITION OF LEFT VENTRICULAR FAILURE WITHOUT RIGHT VENTRICULAR FAILURE

Why is it so important to recognize left ventricular failure? Because it is so amenable to treatment. Contrary to the idea expressed by so many of the English school in our own generation digitalis is usually a great aid in the treatment of the left-sided heart failure even though the cardiac rhythm in such cases generally is regular. If auricular fibrillation happens to be present, so much the better, but the idea that it must be present to permit benefit from digitalis is certainly wrong. This has been pointed out clearly by Christian²⁸. Experience with many cases in the past ten years has convinced me of the truth of his teaching. The case here reported is a clear example. Of course, rest as well as digitalis

one pill three times a day after meals for the first week (21 Gm.) followed by one pill (0.1 Gm.) daily thereafter without making any other change in his activities. Two weeks later, March 15, he returned to the clinic feeling perfectly well without dyspnea and stronger and more fit than he had been for a long time. The changes in the significant observations are given in table 2. The electrocardiogram showed no change except that the heart rate had dropped from 100 to 80 and there was evidence of the effect of digitalis on the T waves.

SUMMARY AND CONCLUSIONS

Weakness and congestive failure of the left ventricle are common whether or not there is an associated right ventricular failure. It is important to recognize this fact and to be able to diagnose the condition, since treatment by the administration of digitalis by rest, or by both these measures is usually of great help even though the heart rhythm is normal and even though there is no evidence of congestion of the systemic veins.

The left ventricle is the primary site of strain four to five times more often than is the right ventricle, essential hypertension, myocardial infarction from coronary thrombosis (which rarely involves the right ventricle), and aortic valve disease exceeding in total frequency mitral stenosis, pulmonary valve stenosis.

TABLE 2—Observations in Case of J. M.

Date	Digitalized	Paroxysmal Dyspnea	Proto- diastolic Gallop Rhythm	Pulsus Alternans	A ₂ and P ₂	Vital Capacity Cc	Orthodiagram		Pulse Rate	Blood Pressure	
							Area Lung Hilus Shadows Sq. Cm.	Area Heart Shadow, Sq. Cm.		Systolic	Diastolic
March 1	0	+	+	0	P > A ₂	3,000	26.5	152	90	170	125
March 15	+	0	0	0	A > P ₂	3,500	13.0	150	78	175	110

and sometimes, if necessary, diuretics may afford much relief but digitalis alone may turn the scale as in the present case, which can be easily and often duplicated.

REPORT OF CASE

A man, aged 57, a clerk, reported to the Cardiac Clinic of the Massachusetts General Hospital, March 1, 1933, complaining of a slight sense of smothering at night, which had forced him to use two pillows during the previous month. There had been a slight cough. Examination showed no abnormalities except for considerable cardiac enlargement (the apex impulse and the left border of dullness in the sixth left intercostal space, 11 cm. from the midsternum and 3 cm. beyond the midclavicular line) accentuated pulmonary second sound, which was louder than the aortic second sound, a protodiastolic gallop rhythm at the cardiac apex, a loud blowing apical systolic murmur, and hypertension (systolic blood pressure 170 to 175 mm. of mercury in both arms and diastolic pressure 125). There was no engorgement of the cervical veins, the liver was not enlarged and there was no edema of the legs or feet. An electrocardiogram showed normal rhythm at a rate of 100, abnormal left axis deviation (angle of -41 degrees), slight widening of the QRS waves and inverted QRS. Vital capacity was 3,000 cc. (the best of three tries). An orthodiagram showed marked general cardiac enlargement, the measurements were as follows: from the midline to the most distant right border, 53 cm., to the most distant left border, 113 cm., transverse diameter, 16.66 cm., long diameter, 15.6 cm., internal diameter of thorax, 25.4 cm., cardiothoracic ratio, 61 per cent, great vessels 4.8 cm., cardiac area, 152 square centimeters. The hilus shadow area was right, 19.6 square centimeters, left, 6.9 square centimeters.

The patient was given digitalis in the form of pills, each of 0.1 Gm. (1½ grains), of the dried leaf, and was told to take

and pulmonary disease sufficient in degree to be a strain. Cases of heart failure without obvious factors of strain like those mentioned are not common. The most frequent cause of strain on, and enlargement and failure of, the right ventricle is left ventricular failure.

There are several important symptoms and signs that point to weakness and failure of the left ventricle and which should permit its recognition in the absence of mitral stenosis and congenital heart disease, they are (1) cardiac dyspnea, (2) cardiac asthma or acute pulmonary edema, (3) diminishing vital capacity due to heart disease, (4) engorgement of the roentgen shadows of the lung hilus blood vessels, (5) protodiastolic gallop rhythm at the cardiac apex in the absence of heart block, (6) pulsus alternans, and (7) increasing accentuation of the pulmonary second heart sound. The failure in the past easily to visualize congested blood vessels in the lungs undoubtedly accounts for the unwarranted preponderant emphasis placed on increase of systemic venous pressure in congestive heart failure.

Massachusetts General Hospital.

Character, Knowledge and Skill.—The family physician, then, as he has adjusted himself to the demands of society, though temporarily overshadowed by the specialist, in all probability more nearly meets the needs of our civilization in caring for the great majority of illnesses than would any figmentary figure which one might devise. His effectiveness in his field of activity depends upon character, knowledge and skill, rather than upon material resources or organization. The problem is to attract such men into the profession of medicine and then properly educate them—matters which are neither new nor unappreciated.—Harvey, S. C. *Oikonomia Medika, Yale J Biol & Med* 5:323 (March) 1933.

FOOD POISONING DUE TO
STAPHYLOCOCCI

REPORT OF AN OUTBREAK

RALPH McBURNEY, MD
UNIVERSITY, ALA

The exhaustive study of the subject of food poisoning in Great Britain by Savage and White¹ covered a period of several years. One hundred outbreaks were involved, incriminating such foodstuffs as cooked meats, fish fowl, cheese, milk, cake and canned goods of various sorts. The organisms chiefly concerned were *Bacillus aeterycke*, to which they attribute three fourths of these cases. Next found in order of frequency was *Bacillus enteritidis* of Gürtner. From all evidence accumulated, as the result of a number of years' study, they have not found a single instance in which *Bacillus paratyphosus* B was the cause. Further, they feel that cases reported as due to *B. paratyphosus* B were in reality due to *B. aeterycke*, since all strains of paratyphoid bacilli studied came from paratyphoid fever and none possessed the irritant qualities necessary to produce the typical facies of acute food poisoning.

As far as I have been able to ascertain in going over the literature, no cases of acute gastro-enteritis due to staphylococci have been reported by these or other workers as occurring in Great Britain. There were eight outbreaks from poisonous cheese in their studies. One of these, they found, was due to organisms of the *Salmonella* group (*B. supester*). In the other seven they failed to find any of the organisms of this group nor did they find evidence of the substance tyrotoxin, detected in poisonous cheese by Vaughan,² but later refuted by him as the cause of poisoning from such sources.

Staphylococci as a cause of acute food poisoning outbreaks were not recorded in the literature until 1914, when Barber³ reported the occurrence of cases of acute gastro-enteritis on a farm in the Philippines from milk of a certain cow. Cases did not occur from ingestion of fresh refrigerated milk but from milk kept at room temperature. He isolated a yellow and a white staphylococcus from the milk. The white staphylococcus inoculated into preserved milk produced symptoms in the investigator while the yellow one did not.

In 1930, Dack and his co-workers⁴ reported finding a yellow staphylococcus in samples from a Christmas cake, which had caused acute gastro-enteritis in ten persons in Chicago in 1929. Bacteria-free filtrates produced by growing the organisms from two to three days at 37°C produced violent gastro-intestinal symptoms when fed to human volunteers in quantities of from 2 to 10 cc.

The same year Jordan⁵ reported an outbreak of acute food poisoning occurring in Puerto Rico and affecting four persons. From a sample of cheese sent to him he isolated yellow staphylococci. Broth filtrates prepared in the way mentioned produced typical gastro-

intestinal symptoms when fed to three human volunteers. In 1931, Jordan and Hall⁶ reported another instance in which two persons in the Panama Canal Zone were made ill and in which case staphylococci were isolated from chicken gravy. Broth filtrates likewise produced typical symptoms in several human volunteers.

In 1931, Jordan⁷ reported an outbreak due to yellow hemolytic staphylococci isolated by Dr G M Dack at the laboratories of the University of Chicago from specimens of devil's food layer cake purchased at a store in Milwaukee, which caused acute illness in four persons. Broth filtrates produced gastro-enteritis in two of three human volunteers when given as little as 2 cc in pasteurized milk. Two others, given 5 cc in the same manner, were likewise affected. Two human volunteers who ate some of an experimental cake inoculated with some of the organisms were also made ill.

Ramsey and Tracey,⁸ in 1931, reported, from a study of malt flavor in milk the isolation of an orange colored staphylococcus thought to be the cause of "off flavor." Tasting milk inoculated with the organism produced violent symptoms of acute gastro-enteritis in one of the authors (Ramsey). In 1932, Tanner and Ramsey⁹ working with the same organism, state that several of a group of twenty individuals who visited the laboratory for the purpose of testing "off taste" of milk inoculated with the organism reported that they were made ill, and that one member of the staff was made ill from drinking pure cultures of the organism. Jordan,⁷ who reviews the literature in connection with food poisoning outbreaks, cites eight in which staphylococci, while not absolutely incriminated by the experimental feeding of human volunteers, certainly appear from all the evidence presented, to have been the cause.

In addition to this accumulated evidence, incriminating staphylococci as the cause of at least six food poisoning outbreaks, a seventh recently studied is herein reported.

Following a dinner served to women students at a southern educational institution, at which chocolate eclairs were served as dessert, there was a severe outbreak of acute gastro-enteritis. There were 150 marked cases. Of these, 75 were very severe, the remainder, less so. In addition, there were a number of others who complained of slight nausea and weakness and a few cases reported later but not seen by attending physicians. There were approximately 325 persons who ate eclairs. Those who did not were not affected. There were a few visitors made ill, who ate dinner elsewhere and partook only of eclairs. Quite a number of the girls took the eclairs to their room, eating them around 6 p m and becoming ill about 9 o'clock. These constituted the most severe cases. Not a single person who did not eat eclairs was made ill.

In checking up, as far as it was possible to do so, it is safe to estimate that at least 60 or 70 per cent of those who ate eclairs were affected to a degree. In the majority of cases, attacks were initiated within two or three hours following the meal, which was served at 1 p m.

The eclairs were made by a local bakery. The pastry shells were made the day before and kept in the original baking pans. The custard filler was made that morning.

and the shells were filled by means of a pressure gun, shells being held in the hand of the worker while being filled. Delivery was made about 11 a. m. The eclairs were kept at room temperature and served about 1:30 p. m.

There were several batches of eclairs. All were made of similar batches of ingredients but were not all filled with custard at the same time.

This fact, individual resistance or the ingestion by some of relatively small portions of the pastry or the fact that some of the eclairs contained few or no organisms may account for the fact that more of those who ate eclairs were not made ill.

Symptoms were marked by nausea, salivation, abdominal pain, vomiting, extreme prostration, profuse diarrheal attacks, and chilliness. Some vomited at intervals of from ten to fifteen minutes and as many as twenty to thirty times. A few vomited throughout the night. Vomiting attacks became further spaced in some and in other patients ceased suddenly as they became better. Diarrheal attacks averaged from six to eight. Of the seventy-five pronounced cases five patients, were near collapse. Three had a weak, rapid pulse

Action of the Filtrates on the Seven Volunteers

	Minimum	Average	Maximum
Time before symptoms appeared	1 h 45 m	2 h 15 m	3 h
Time before vomiting began	2 h	3 h	3 h 20 m
Number of vomiting spells	3	9	14
Interval between spells	10 m	15 m	20 m
Vomiting persisted	1 h 5 m	2 h 30 m	4 h
Time before diarrhea began	2 h 30 m	3 h	4 h
Time following onset of vomiting	15 m	Coincident with	40 m
Number of diarrheal attacks	2	5	13
Diarrhea persisted	2 h	3 h 50 m	7 h
Time elapsed before felt relief	3 h	5 h 30 m	10 h
Time elapsed before complete recovery	5 h	17 h	48 h
Complaints following recovery: general weakness, soreness of abdominal muscles and slight headache			

Blood pressures were not taken, since the attention of two attending physicians was focused on relieving the acute symptoms.

The short incubation period (from two to three hours), the symptoms and the facts regarding the eating of the eclairs led to the supposition that a staphylococcus was involved. As a matter of routine, dilution plates with Endo's medium were made of some of the custard filler and from the pastry. Numerous golden yellow staphylococcus colonies resulted, but nothing resembling the Salmonella group was observed. Agar dilution plates of the filler and crust likewise produced numerous golden yellow colonies, which proved to be staphylococci. Five different colonies were picked from different plates. Bacteria-free broth filtrates were prepared from forty-eight hour cultures of these organisms. Similar filtrates were prepared from two of four cultures sent me through the kindness of Dr. Leon C. Havens, director of laboratories, Alabama State Department of Health, to which some of the eclairs were sent by the local food and milk inspector. Ten cubic centimeter quantities of these filtrates were fed to each of eight volunteer medical students in 200 cc of pasteurized milk. As controls, four students were given similar amounts of sterile broth of the same batch used for growing the organisms. This was likewise given in 200 cc of pasteurized milk. The dosages were given numbers and mixed, so that no one knew whether he

was getting plain or toxic broth. Of those receiving the bacterial filtrate, all were ill except one, he was slightly nauseated and felt weak. None of the controls were affected. The minimum period of onset was one hour and forty-five minutes, and the maximum period three hours. Symptoms were nausea, salivation, vomiting, diarrhea, extreme prostration, chilliness, sweating, abdominal pain and tetanic muscular contraction, especially of the flexors of the legs. These contractions were followed by intense muscular pains. All symptoms were manifestly similar to those exhibited by the girls who were sick following the meal.

Some of these volunteers were extremely ill, vomiting blood and bile and passing bloody stools. Several described their feelings to me by saying that if death was necessary for relief they were ready to die. Several, in attempting to walk upstairs to their rooms collapsed. Complete recovery occurred among all the accidental victims and the volunteers.

COMMENT

As has been the case with other workers who have reported food poisoning outbreaks due to staphylococci, the source of contamination of the eclairs could not be traced. Thorough bacteriologic examination of all ingredients used in the preparation of the custard filler and in preparation of the cake substance failed to show any organisms of the aureus variety. Those organisms present were comparatively few in number. Cooking experiments conducted at the bakery following inoculation of custard filler with staphylococci isolated from the eclairs showed that the heating process employed in making the custard destroyed them, as many as 2,500,000 staphylococci per cubic centimeter of liquid custard being completely destroyed by the cooking process, which is done at 185 F (85 C) for ten minutes. These experiments will be described in a subsequent paper. The bakery was scrupulously clean. No history of recent illness of any of the employees, colds, furunculosis, sore throats or hand infections could be elicited. It is probable, however, that contamination of the custard or pastry might take place during the cooling of the custard or filling of the pastry shells. As previously stated, they were filled by hand, a pressure gun being used to express the custard into the pastry shell. These so-called guns are constructed so that they are not easily cleaned. Considerable film of dried custard was noted in the one used in this particular instance, but, unfortunately, was seen too late for a satisfactory bacteriologic examination. Similarly, custard filler prepared and allowed to stand uncovered for several hours might easily become contaminated with virulent staphylococci through coughing and sneezing of the bakery personnel in making and handling them. If filled eclairs are allowed to stand at room temperature for a considerable period, it is easy to understand how heavy contamination might take place. Possible contamination following delivery might likewise be considered. Experiments in connection with these factors are now in progress.

SUMMARY

There have been, as far as could be ascertained, six well defined outbreaks of food poisoning due to staphylococci, proved epidemiologically and by production of symptoms in human feeding experiments. The outbreak of food poisoning due to a golden yellow staphylococcus here reported is the seventh.

Of the seven outbreaks, two were traced to milk, two to cake, one to cheese, one to chicken gravy, and one to chocolate eclairs. All such outbreaks reported have occurred in the United States or its possessions. The history, short period of onset and acute symptoms studied in cases and human volunteers should clearly point to the etiologic factor involved in future outbreaks.

It is probable that a large number of outbreaks of food poisoning in this country and elsewhere, in which the etiologic factor has not been determined, have been due to organisms of the staphylococcus group.

The source of contamination of food with these organisms has not yet been definitely ascertained. Pointing, however, to man himself, it appears that pastries, custard fillers, and the like, should be well protected against possible contamination in preparation and storage and that cheap cotton, paper or cellophane¹⁰ mittens might be used in bakeries in the handling of the finished products. Custard fillers should be refrigerated immediately following preparation until ready for use. After baking, cakes and pastries should be covered or placed in especially constructed cases and not left about in the open or on tables where they may be exposed to contamination from the coughing and sneezing of bakery personnel. These precautions could well apply to the storage and handling following delivery, especially in institutions where a large kitchen force is employed.

METHYLENE BLUE A SYNERGIST, NOT AN ANTIDOTE, FOR CARBON MONOXIDE

HOWARD W. HAGGARD, M.D.

AND

LEON A. GREENBERG, Ph.D.

NEW HAVEN, CONN.

Methylene blue (methylthionine chloride U. S. P.) has recently been much in the lay press, not only as an antidote for cyanide, which it is, but also for carbon monoxide, which it is not.

P. J. Hanzlik¹ has reviewed the evidence that this substance is an antidote to cyanide. As he points out, the antagonistic property of methylene blue for cyanide was demonstrated experimentally as early as 1926 and has been confirmed by more recent work.

On the other hand, the alleged antagonism between methylene blue and carbon monoxide has no valid support. The theoretical basis of the claim for an antidotal action is derived from the brilliant investigations of Warburg,² but Warburg's observations on isolated tissues have no real bearing on carbon monoxide asphyxia in man. The experiments of Matilda M. Brooks³ on animals are of little evidential value. The fact is that in its effect on man and other red-blooded animals, methylene blue acts, not as an antidote for carbon monoxide, but as a synergist. It not only fails to relieve carbon monoxide asphyxia, it may even induce fatalities that would not otherwise have resulted.

THE DISTINCTION BETWEEN CYANIDE POISONING AND CARBON MONOXIDE ASPHYXIA

The idea that methylene blue might be an antidote for carbon monoxide rests on an almost complete misapprehension of the physiology of carbon monoxide asphyxia. It is based on the assumption that carbon monoxide in the amounts generally fatal acts like cyanide by interfering with the oxidative ferment of the tissues. Warburg has indeed shown that even small amounts of cyanide may inhibit the action of this ferment and thus abolish the ability of the tissues to use oxygen.

Warburg has shown further that, when methylene blue is applied to isolated tissues, it tends to counteract the influence of cyanide on the tissue ferment. In this fact there is an apparent theoretical basis for the belief that methylene blue might counteract the effects of cyanide in the living body. In reality, as is now known, this is not the explanation of the antidotal action of methylene blue for cyanide in living red-blooded animals or human beings. It applies only to bloodless tissues.

Warburg has likewise shown that carbon monoxide may combine with the tissue ferment and inhibit its activity. But as Warburg himself recognizes, the concentrations of carbon monoxide which are immediately fatal to men and animals are far lower than those which have any appreciable influence on the respiratory ferment of the tissues. The ferment has an affinity for carbon monoxide which is several thousand times less than that of hemoglobin for this gas. In experiments designed to show the inhibitory action of this gas on the ferment in isolated tissues it is therefore necessary to employ concentrations of carbon monoxide about a thousand times greater than those which kill men and animals. Warburg, working with tissues free from hemoglobin, used atmospheres of 95 per cent of carbon monoxide and only 5 per cent of oxygen. The hemoglobin of the blood, on the contrary, even in the presence of 21 per cent of oxygen and only 0.1 per cent of carbon monoxide, combines with the carbon monoxide to a fatal degree. For these reasons very small amounts of carbon monoxide are required to kill a man, while enormous concentrations are required to affect the respiratory ferment to any appreciable degree.

In further support of this view it may be recalled that Haggard⁴ has shown that the nerve cells of the chick, when cultivated in vitro, will live and grow normally in the presence of 80 per cent of carbon monoxide and 20 per cent oxygen, and likewise that the elder Haldane⁵ has shown that insects, which have no hemoglobin but which do have tissue ferment, are not in the least affected by an atmosphere containing 80 per cent of carbon monoxide and 20 per cent of oxygen. The same insects are, however, readily poisoned by small amounts of cyanide. Asphyxia from carbon monoxide results, then, not from inability of the tissues to utilize oxygen but from deficiency of oxygen in the blood. Methylene blue does not increase the supply of oxygen.

Furthermore recent work by Wendel⁶ indicates that the antidotal action of methylene blue for cyanide is

to be found, not primarily in the action of this dye on the tissue ferment, but in an effect of the dye on the hemoglobin of the blood somewhat resembling that of carbon monoxide. Methylene blue converts hemoglobin into methemoglobin. Cyanide combines with methemoglobin. The formation of methemoglobin and the resulting withdrawal of cyanide from the blood and tissues in the formation of cyanmethemoglobin thus reduces the concentration of cyanide free to act as a poison on the tissue ferment. In this reaction of cyanide with the methemoglobin formed under the influence of methylene blue, rather than in any counteraction of the dye on the tissue ferment is to be found the antidotal effect of methylene blue in cyanide poisoning.

This reaction of the dye in the blood, although beneficial in cyanide poisoning, is extremely harmful in carbon monoxide poisoning. Carbon monoxide exerts its poisonous effect by combining with hemoglobin and rendering it temporarily incapable of carrying oxygen. Methemoglobin is also incapable of carrying oxygen. The conversion of a portion of the hemoglobin of the blood into methemoglobin, instead of benefiting the anoxemia, exaggerates it. Thus on theoretical grounds methylene blue is definitely contraindicated in carbon monoxide poisoning. The experimental work to be here reported shows that its use intensifies asphyxia, delays recovery, and promotes death.

The administration of methylene blue in cases of carbon monoxide poisoning, as reported recently in the lay press, has generally been made after the patients had already eliminated a large part of the carbon monoxide that they had absorbed. This statement is true also of the cases reported by Geiger.⁷ We agree with him that they show no definite advantage from treatment with methylene blue. After removal of the victim from the atmosphere of carbon monoxide, the elimination of the gas from its combination with hemoglobin is especially rapid when inhalation of oxygen and carbon dioxide is administered, as in most of the cases reported. The concentration of carbon monoxide in the blood may fall 20 or 30 per cent or more even in a quarter of an hour. In such cases the administration of methylene blue may not be fatal, but neither is it beneficial.

THE INFLUENCE OF "COUNTERSHOCK"

In the experiments of Brooks in support of the claim for the antidotal action of methylene blue, rats were exposed to approximately 1 per cent of carbon monoxide until unconsciousness developed, when they were removed from the gassing chamber. Some of the animals were then injected with a solution of methylene blue, while others were allowed to recover untreated. The criterion used for recovery was the ability of the rat "to run straight forward." It was found that the rats treated with methylene blue met this requirement in about half the time required for the untreated rats.

It is noteworthy that in these observations of Brooks the control rats were not injected even with saline solution. This point is of considerable importance, for in animals as small as rats, even without any treatment, the blood is quickly cleared of carbon monoxide, and recovery, if the animal recovers at all, is extremely rapid. During the period of recovery any strong sen-

sory stimulus, particularly one involving pain such as puncture with a hypodermic needle, may induce both a psychic and a motor response. This well known fact is the basis of one of the many fallacious methods that have from time to time been suggested for the treatment of carbon monoxide poisoning, namely, "countershock." It has been observed on men that pain caused by slapping the face, pounding the soles of the feet or stretching the anal sphincter will sometimes hasten the return of consciousness. In one of the booklets telling employees of electric light companies how to resuscitate men from electrocution, this procedure of mechanical "countershock" was recommended. It was accompanied by a photograph showing an unconscious man with a hatchet placed suggestively beside him.

From our data it appears that the rats in the experiments of Brooks were subjected to "countershock." They walked quicker, if not straighter, because the pain of the injection woke them up. If a needle had been stuck into the control rats, as was done in our experiments, they would have waked up also.

EXPERIMENTS ON RATS

In our experiments the time required to produce death under inhalation of carbon monoxide was determined for rats injected with methylene blue and for rats injected with an equal quantity of saline solution. The carbon monoxide content of the blood at death was determined in each case. Six rats, all of the same weight, three with methylene blue, 20 mg per kilogram, and three with saline solution, were placed under one large bell jar. Sufficient carbon monoxide was run in to make a concentration of 0.5 per cent in the air of the jar. The rats receiving methylene blue were labeled respectively a, b and c, the rats with saline solution were d, e and f. Failure of respiration was taken as the death point, although in each case the heart continued to beat for a short time. Rats a, b and c died in 26, 30 and 33 minutes, respectively. Rats d, e and f died in 25, 29 and 35 minutes, respectively. The total times for each group were identical, 89 minutes, or an individual average of 29 minutes and 40 seconds. The methylene blue did not prolong the time required for the carbon monoxide to kill.

The rats were removed from the jar and on each a determination was made of the percentage saturation of the blood with carbon monoxide. The tannic-pyrogallous acid method of Sayers and Yant⁸ was used, which can be read colorimetrically to about 5 per cent. The blood of each rat, alike those with methylene blue and those without, showed between 80 and 85 per cent saturation. The rats receiving methylene blue did not show a higher degree of saturation than did the control rats. If methylene blue diminished the affinity of hemoglobin for carbon monoxide, this comparison would have demonstrated it. If it protected or aided the oxidative ferment of the tissues or in any other way acted as an antidote, the methylene blue rats would have outlived the others.

In the next experiment, ten rats of equal weight were placed under a bell jar and gassed as in the previous experiment. When almost at the point of death, they were all removed at once and five, chosen at random by a disinterested person, were injected with a methylene blue solution of 20 mg per kilogram. The other five were injected with a similar volume of saline solu-

⁸ Sayers, R. R. and Yant, W. P. The Tannic Acid Method for the Quantitative Determination of Carbon Monoxide in the Blood. Bureau of Mines Technical Paper 2356. May 1922.

tion The time required for recovery was then noted Our choice of a criterion for recovery differed somewhat from that of Brooks, for we find that even normal rats in Connecticut do not without considerable urging "run straight forward" We placed all of the unconscious rats on their backs and used as the index of recovery the righting reaction when the animals of their own accord rolled over and assumed their normal posture The times required for this degree of recovery in the rats treated with methylene blue were respectively 5, 5, 7, 8 and 8 minutes, a total of 33 minutes, for the rats receiving saline solution the times were 4, 5, 7, 7 and 8, a total of 31 minutes

EXPERIMENTS ON DOGS

A second series of experiments was carried out with dogs as the experimental animals Seven dogs were gassed with carbon monoxide to a point just short of respiratory failure On removal from the atmosphere of carbon monoxide, a blood sample was drawn and the percentage saturation of the hemoglobin was determined by means of the Van Slyke blood gas analysis

Comparative Results on Dogs Treated with Methylene Blue and the Untreated Controls After Carbon Monoxide Asphyxia*

Animals Treated with Methylene Blue	Percentage Saturation with Carbon Monoxide			Percentage of Methemoglobin	Condition Next Day
	End of Gassing	Response to Pinch	Able to Walk		
Male 12 Kg	79	65	40	7	Trembling ill and weak
Male, 12 Kg	81	Died 7 minutes after injection			Dead
Female 10 Kg	78	28	14	12	Staggering and ill
Female 10 Kg	82	64	30	8	Very weak
Control Animals					
Female 10 Kg	82	72	45	0	Normal
Female 14 Kg	81	70	50	0	Normal
Male 13 Kg	80	68	46	0	Normal

* The animals receiving methylene blue were responsive to a pinch in 10, 8 and 9 minutes respectively the controls in 10, 12 and 8 minutes Those treated could walk in 20, 24 and 31 minutes the controls in 22, 27 and 20 minutes

apparatus Four of the dogs were at once given methylene blue, 10 mg per kilogram, by intravenous injection The remaining three dogs as controls were injected intravenously with a like volume of physiologic solution of sodium chloride The animals were carefully watched, and as soon as each became sufficiently conscious to respond by moving when pinched on the legs, a second blood sample was drawn A third blood sample was taken at the time the dogs were able to walk after being placed on their feet and urged to move

The percentage of the hemoglobin converted to methemoglobin in the second blood sample was determined by the method of Van Slyke and Hiller⁹ The results of these experiments are given in the accompanying table

It will be seen from this table that the two groups of animals were gassed to almost exactly the same degree In those which were then treated with methylene blue, marked hyperpnea occurred, and the amount of carbon monoxide in the blood decreased more rapidly than in the untreated controls But this advantage

was counterbalanced—indeed, more than counterbalanced—by the formation of methemoglobin and by other deleterious effects The general condition of the treated animals from a quarter to half an hour after the gassing was not better than that of the untreated In fact, one of those that received methylene blue died a few minutes later At the time when the animals first responded to pinching of the legs, the carbon monoxide combined with hemoglobin averaged for the controls 70 per cent with no methemoglobin For the dogs treated with methylene blue the response did not come until the carbon monoxide hemoglobin had fallen to an average of 52 per cent, with from 7 to 12 per cent methemoglobin At the time when the animals were able to walk, the control dogs showed an average carbon monoxide hemoglobin of 48 per cent Those treated with methylene blue showed an average of 28 per cent of carbon monoxide hemoglobin with presumably the same methemoglobin as before

In other words, the control animals were sufficiently recovered from asphyxia to respond to a pinch with only 30 per cent of their hemoglobin free, and to walk with 52 per cent free for the transportation of oxygen The treated animals were not recovered to these degrees until they had 39 and 63 per cent of their hemoglobin again in functionally useful form The difference between these two pairs of figures indicates the accessory ill effects of methylene blue In this respect methylene blue resembles such drugs as cyanide and lobeline

Lobeline also was once advocated as a resuscitant but has now been generally discarded There are many such drugs, all of which induce a temporary increase of respiration and thus promote the elimination of carbon monoxide But no drug has yet been found, with the exception of carbon dioxide diluted in air or oxygen, that has not a greater effect as a poison than as a remedy in the treatment of asphyxia

The most striking difference between the two groups of animals—the controls and those treated with methylene blue—was evident on the following day At that time the control animals were active and appeared in every way normal On the contrary, the dogs that had survived after injection of methylene blue were all ill, they appeared lethargic and their legs shook on standing

CONCLUSIONS

There is no valid basis, theoretical, experimental or clinical, for the belief that methylene blue is an antidote for carbon monoxide asphyxia

The chief effect of methylene blue is to convert some of the hemoglobin of the blood into methemoglobin By thus further diminishing the oxygen carrying capacity of the blood, methylene blue acts as a synergist with carbon monoxide in promoting asphyxia It probably exerts also other deleterious effects

Experimental evidence is here presented showing that the administration of methylene blue in carbon monoxide asphyxia may induce fatalities that would not otherwise occur Illness attributable to the effects of methylene blue persists after recovery from carbon monoxide asphyxia

These conclusions reinforce previous evidence that hypodermic and intravenous medication is more likely to be injurious than remedial in the treatment of carbon monoxide asphyxia¹⁰

PROGRESS IN THE DIAGNOSIS OF TUBERCULOSIS

WITH SPECIAL REFERENCE TO THE X-RAYS

J ARTHUR MYERS, MD

MINNEAPOLIS

During the past five years progress in tuberculosis has advanced very rapidly. Apparently it has been a golden age as far as practical diagnostic, therapeutic and preventive work is concerned. Advances are being made in so many places that it is becoming difficult for one to keep informed on even the major activities. While reading an article on tuberculosis, published about 1917, I was impressed with the quite recent origin of several present well established facts. The contrast was as apparent as that between an article on malaria fever published in 1824 and one published in 1932.

In the first half of the last decade the foundation was laid, and during the second half the superstructure was being built. Controversy and debate have been replaced for the most part by work, which is resulting in actual accomplishment. There are still a few so-called controversial questions such as 1. Is the reinfection which causes illness more often of exogenous or of endogenous origin? 2. Is the first infection which results in a positive tuberculin reaction an asset or a liability to the individual? 3. Is the positive tuberculin reaction a manifestation of allergy or of immunity? 4. Is it possible to produce immunity in the absence of allergy? The new view on some of these questions is contrary to that which many workers were taught as students which they have taught themselves and which they still believe. Doubtless, some of these questions will continue to be controversial, that is every time the members representing the new and the old schools come together, debates will ensue. Such debates stimulate thinking, thinking leads to investigation, not only on the part of the debaters but also on the part of their audience. When such debates are over there is no reason for the existence of personal enmity and malice but every reason why all concerned should go forth seeking every available bit of evidence and producing new evidence. The truth is, most of the remaining points of controversy are not of any great significance in the actual tuberculosis work.

Most workers are agreed on the major factors in prevention, treatment and diagnosis. For example, the ardent advocates for universal infection with tubercle bacilli in infancy and childhood have come to believe that it is now wiser to postpone the first infection with tubercle bacilli, whether of human or of bovine type, just as long as possible. In short, the protection of the body from exposure to tubercle bacilli with the hope that many will live out the span of life without contamination with tubercle bacilli, is the more desirable course. Some are now in a quandary as to whether an avirulent strain of tubercle bacilli such as BCG, should be introduced into human bodies with the hope of producing immunity. This group, at least in America, apparently is very small. It appears that the vast majority of workers prefer to protect against exposure rather than resort to a method of immunization that has been so seriously questioned.

A decade ago, any one who ventured to discuss the tuberculin test from the point of view of its value in diagnosis beyond the period of infancy and early childhood was looked on by many physicians as an impractical enthusiast. Such a physician could rarely find enough persons who agreed with him to debate with members of the opposing school. Some of the profession even tried to discourage veterinarians, who had a vision of tuberculosis control among animals, by discrediting the tuberculin test and stating that eradication of the disease among animals was a physical impossibility. Today, tuberculin is looked on as the most accurate diagnostic agent we possess, both in human and in animal medicine, and the school of physicians that formerly insisted on its lack of practical value has undergone almost total dissolution. For those who have actually used the test extensively, among either human beings or animals, no further evidence is necessary to convince them of its practical value in diagnosis. Most of this change in the point of view has come about during the past five years.

About ten years ago a person who was performing artificial pneumothorax in any considerable number of cases was looked on by many physicians as a dangerous and radical practitioner. To institute artificial pneumothorax when a diagnosis of tuberculosis was first made, regardless of the stage of the disease, was considered almost malpractice. Most physicians believed that such treatment was very drastic and that it should be employed only as a last resort and that no patient should have such treatment instituted until he had been given bed rest for from three to six months or more in the hope that nature would bring the disease under control. Today it is not uncommon for a patient to have his first examination and, if frank pulmonary tuberculosis is detected and the case is suitable for artificial pneumothorax, to have that treatment instituted the same day. To advocate the use of artificial pneumothorax in minimal but progressive tuberculous lesions is no longer looked on as sacrilege. Even to treat carefully selected cases of pulmonary tuberculosis by artificial pneumothorax alone has been found adequate by a number of physicians who have instituted this practice. Such rapid advance in knowledge has taken place during the past five years that today this form of collapse therapy is looked on as a standard method of treatment. Therefore, the large school of physicians who formerly bitterly opposed collapse therapy no longer exists.

About 1920 there was considerable debate as to the value of roentgenograms in the diagnosis of tuberculosis. A school of physicians of considerable size strenuously opposed its use on the ground that physical examination was sufficient. This group has been reduced to a mere handful. The manufacturers of films and other x-ray equipment have done such marvelous work that the finished x-ray film of today is far superior to that of a decade ago. However, much remains to be done before the film becomes a fine screen in diagnosis, nevertheless, it is already sufficiently good that those engaged in practical diagnostic and follow-up work of chest lesions need no further evidence concerning its great value.

What has happened to the physicians who formerly so strenuously opposed the new views concerning diagnosis, treatment and prevention of tuberculosis? They were not executed, they were not driven out of medicine, nor by any means have all of them died. The vast majority of them were working in the light of the

Read in part before the Gibson County Medical Society, Trenton Tenn. March 27 1933 the Chicago Tuberculosis Institute, March 28 1933 the St. Joseph County Medical Society, South Bend, Ind. March 29 1933 and the Peoria City Medical Society, Peoria Ill. April 18 1933.

best knowledge of their time. They were clinging to the teachings of their alma maters, but all the time their minds were open. Nevertheless, they demanded evidence and, as such evidence accrued, one by one they joined the opposing school until today physicians are very much in agreement on the major factors of the diagnosis, treatment and prevention of tuberculosis.

There is very little likelihood that the profession will remain where it is. Perfection is still a long way off and, as the necessities are recognized, a solution will be found. A notable example is the field of tuberculosis surveys. That the tuberculin test is the finest screen for detecting the persons of a community who have foci of tuberculosis in their bodies is no longer doubted, but the tuberculin test is only part of an examination, that the roentgenogram of the chest of positive tuberculin reactors is another part of every satisfactory examination, almost every one admits. The tuberculin test can be administered quickly and cheaply. Therefore, it has been quite extensively used. The previous method of making roentgenograms was a slow one and involved considerable expense. To make films of the chests of large numbers of university students, school children, industrial groups and the like with present equipment has been so slow that often weeks and months elapse after the work is begun before the last chest film is made. If frank tuberculosis is present in the chests of individuals last examined, it has had an opportunity to spread, and the bacilli may have been disseminated to many associates. Thus, the demand has arisen for a rapid method of making roentgenograms of the chest. An attempt to meet this demand was made by the Queensboro Tuberculosis and Health Association and the Powers Photo Engraving Company. To one who has seen the work of these organizations almost in its beginning, 1931, and followed it subsequently, it is most striking how in such a short time the demand for a rapid method of making x-ray films of the chest could be met so well.

The first problem was to produce a film that required as little handling as possible. The result was x-ray paper films in rolls each roll large enough for 100 or more exposures. The next need was to make many exposures in a short time. This was met by the use of special attachments to the x-ray equipment, some of which were automatic, and a water-cooled x-ray tube. Already a device is in use which easily makes 150 exposures an hour. This rate can be maintained for five or six hours a day with two operators and for eight or ten hours a day with three operators. Under pressure of time, as many as four exposures have been made in a minute. The roll of film is developed intact, after which it is quickly dried. The developed roll is then placed in a special device, where in a short time all the pictures can be viewed.

Paper x-ray films have been produced several times in the past. In fact, the subject of paper films in chest radiography has been favorably¹ and unfavorably discussed.² However, in neither did the new film recently produced in New York come under consideration. Apparently, this new film is definitely superior to any previously manufactured.

Some questions naturally arise, such as What are the advantages and disadvantages of these films from the standpoint of diagnosis and the like? Where have they been used? and What has been the result? Barnard,

Amberson and Loew³ made exposures first on celluloid film, then on the new paper film in 1,000 cases. They then made a comparative study of the two methods. They say

Paper films used by us do not produce chest roentgenograms of quite the same clearness as do celluloid films. The difference, however, is not sufficient greatly to impair the value of the paper film for practical diagnostic purposes. In the interest of public health, the slight diagnostic error would be much more than offset by the possibility of examining larger groups of people by this method. In view of the smaller expense, we therefore believe that the paper film may be advantageously used for chest roentgenograms of large groups of school children or other persons, provided those with doubtful shadows are again x-rayed with a celluloid film. The paper film may also be found useful for other purposes by some workers according to their peculiar needs.

From personal observation, I am firmly convinced that the paper film is of value not only in diagnostic work but also in making serial x-ray records of lesions after they have been detected. Such records have become necessary in studying the effect of treatment on pulmonary lesions. In cases on collapse therapy, particularly pneumothorax and phrenic exeresis, the paper film records the extent of collapse and like conditions excellently. I am told by those engaged in other phases of medicine such as orthopedics, that the paper film in its present stage of development is adequate for a considerable part of their x-ray work. Other advantages cited are that the paper film burns more slowly than uncoated paper and gives off no noxious fumes when burning and that data concerning the patient may be written on the front or back of the developed film.

Paper film in rolls has been used in making exposures of chests of about 11,000 school children in Queensboro (these children are to be reexamined by x-rays every year for about four years), the entering class of the Bellevue Medical College (1932), 6,000 high school and junior high school students in New Haven, Conn., and about 11,000 children and adults in the Harlem district of New York. In addition to the rapid camera work, paper films for ordinary single and stereoscopic roentgenograms are now in use in several states, including Illinois, Indiana, New Jersey, Montana, Virginia, Alabama, Ohio, Minnesota and Massachusetts. The cost of the paper film is approximately half that of the ordinary film, so that when the rapid method is used, which necessitates so little handling of film, the cost of the finished product is markedly reduced.

There is one danger against which the medical profession must guard, it is that this rapid method of making x-ray films and the necessary equipment may get into the hands of those who are overenthusiastic and unqualified, as heliotherapy did. The manufacturers are anxious to prevent this and are ready to cooperate fully with the medical profession. Although the paper film is not all that one desires, it is still very much worth while. No one has claimed that it is superior to the modern transparent film in clarity. However, it is highly satisfactory when properly used in case-finding work. Moreover, from the standpoint of clarity, the paper film of today is superior to the

celluloid film of a few years ago. The manufacturers have definitely improved the paper film from time to time and are of the opinion that it will be further improved in the near future. The first consideration of the entire medical profession is the control of disease, hence such an advancement as the rapid method of exposing and developing x-ray films and the manufacture of the paper film should be accepted with alacrity. Here is a method which will make possible the use of that very valuable diagnostic aid the x-ray film for large groups of people who would otherwise be denied it. Wherever a survey is to be made, it should be not only with the consent but under the direction of the local medical society. This will insure the keeping of the survey on a sound foundation so the tuberculin tests and x-ray films will be properly interpreted, and those found to have evidence of disease can be referred to their family physicians for any necessary treatment.

The following statements by Dr. John L. Rice,⁴ health officer of New Haven, Conn., confirm some of these statements and illustrate its use.

During the month of November [1932] the New Haven Department of Health and the Board of Education undertook a special piece of tuberculosis prevention work among school children. Within a period of eleven school days, 6,400 children of high school and upper grade age had chest x-ray pictures taken. The pictures of all pupils except ninety were paid for by the respective parents. Recently a new method of obtaining x-ray pictures has been devised and its value demonstrated. In this new method the pictures are taken on paper instead of celluloid. The paper films are utilized in rolls and the portable x-ray apparatus so regulated that pictures can be taken at the rate of three to four a minute. The films are developed in rolls of a hundred or more exposures and interpreted under reflected light by merely unrolling the long sheets on an appropriate apparatus.

This large group of x-ray pictures is now being studied by Dr. Edwards. The pictures will eventually be returned to the pupils after the information of value has been put in the hands of the family physicians. Many physicians and x-ray men have seen these pictures and there is surprise and enthusiasm at the uniformity, clarity and detail presented. It will be some time before all of the pictures are studied and interpreted, but the first 700 high school students studied and perhaps the best group physically, show 91 per cent of suspicious or manifest disease as follows: suspicious 55 per cent, childhood type, 3.2 per cent and adult type, 0.4 per cent.

This work will make it possible to pick out the children who have had enough infection to have produced a variable amount of disease which can be seen in a picture. It will also provide an opening to follow into homes and perhaps discover unrecognized sources of infection.

In any such survey, the medical profession must be extremely careful that the public is informed that the low cost is solely for survey work, since it does not include interpretation of the film. The charge for roentgen examinations in the private practice of medicine has never been based on the cost of materials but rather, as it should be, on the professional knowledge required to interpret the shadows. Any one can look at an x-ray film, but to be able to interpret it properly requires long years of training. When a physician is called to the home of a sick person, his fee for such consultation is not based on the instruments and materials used, for they may consist only of a stethoscope, but his special senses have, through years of training, been so developed that through them he is able to elicit evidence which is most apt to lead to an accurate diagnosis. Again, his years of training in

therapy lead to advocacy of such therapeutic measures as will result in the best chances of recovery for the patient. In prescribing the treatment, perhaps all he uses is a pen and a prescription blank. His fee is based on his ability to diagnose and treat the disease, rather than on actual materials used. The same situation obtains in the interpretation of an x-ray film. With survey work the cost to date for x-ray films has included practically nothing but material. The interpretation of the films has for the most part been an act of charity on the part of physicians. In private practice the difference between the cost of paper and celluloid films is an insignificant part of the charge to each individual patient, but, if a medical society cooperating with a tuberculosis society with limited funds desires to make films of the chests of 100,000 persons who otherwise would not have x-ray film work done, the difference in cost of materials alone would be approximately \$30,000.

Tuberculosis surveys often bring to light some very definite but unsuspected cases of tuberculosis. Such results prove to the public the great value—in fact, the necessity—of the x-ray film as a part of an examination. This new x-ray development is another advantage that our predecessors lacked.

SUMMARY

Although there are still a few controversial subjects in the field of tuberculosis, they are of minor significance. Ten years of careful observation and study has resulted in complete reversal of the views in the major factors of this work, such as the tuberculin test and the roentgen examination.

Transparent x-ray films now in general use have been greatly improved in the past decade but still are not all that could be desired.

The present equipment for making x-ray films is too slow in operation for the increased demands for greater numbers of x-ray examinations. The new rapid x-ray camera meets the demand by making with ease from 500 to 1,000 exposures a day.

The new paper x-ray film in rolls has reduced the cost of films by about one half.

No one has claimed that the paper film yet reveals the same detail as the transparent film, but the difference in clarity is slight. Conservative observers with much experience have estimated it to be not more than 10 per cent.

The new paper film, at least in its present state of development, will not displace the transparent film for certain types of work. Those who have accomplished so much by way of refining the transparent film should be encouraged to continue their efforts to improve it, with the hope that eventually it will reveal much more detail than it does at present.

The new paper x-ray film should not affect the cost of x-ray work in private practice, since the major part of the charge made the patient in the past has been based on the physician's ability to interpret the shadows.

The medical profession should support this rapid and much cheaper method of making roentgen examinations, since it has real merit and since it makes roentgen examinations possible for large numbers of persons who otherwise would not have them. By so doing, it will be kept out of the hands of unqualified individuals and organizations, yet it will be fully utilized within the limits of medical science.

ASPERGILLOSIS A CASE OF POSTOPERATIVE SKIN INFECTION

LOUIS FRANK M.D. AND O. M. ALTON, B.S.
LOUISVILLE, KY

Since our student days we have been familiar with the fact that molds may at times be pathogenic in their action. Attention had been called to this pathogenicity even before Virchow's work in 1856 describing the infectious process and identifying the organism. Baumgarten in his "Mykologie," published in 1890, describes the lesions resulting from experimental injections of *Aspergillus niger* and discusses very fully the pathologic changes and the microscopic observations.

Myers and Dunn¹ reported a case of aspergillosis in which the infection was located on the dorsal aspect of the hand of a farmer. The lesion was in the nature of a granuloma.

Most often this infection is seen in the auditory canal and in the lungs. In the lung it may run a very chronic course and defy accurate diagnosis for a long time. In the auditory canal it is a question whether the mold acts as a true pathogenic organism or is present as an epiphyte. In the lung, however, it is truly parasitic or pathogenic in character.

Recently our attention has been called to a postoperative dermatosis due to *Aspergillus* and, having seen two previous cases, we have thought the matter of sufficient interest to record, also, we have noted no similar postoperative skin infections reported in the literature.

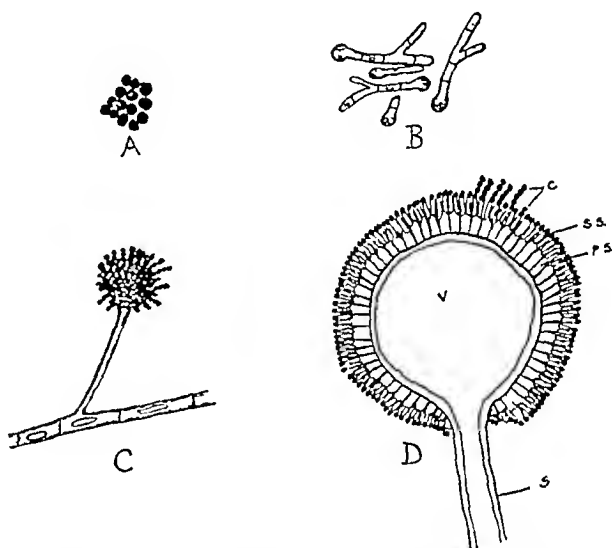

A woman, aged 40, was operated on for abdominal tumor, the operation being devoid of any feature worthy of comment. The usual preoperative local preparations were made and the usual dressings applied. At the end of about sixteen days, the dressings were removed and revealed what has been observed on two other occasions, namely, the dressing had the appearance of being studded with black powder, and at one end of the wound, near the site of one of the lower stay sutures, there was a spot that had the appearance of a large ulcer, about 1½ inches (37 cm.) in diameter, with sharply defined edges, slightly elevated and filled with a yellowish-black material resembling pus. In addition, at various points in the skin under the gauze dressings covering the wound were pustules varying in size from one-sixth to one-fourth or three-eighths inch in diameter. They were elevated, contained a purulent looking material varying in color from yellowish, in the smaller, to almost black in the larger pustules. They were quite superficial and did not penetrate through the true skin except for the large ulcer-like area at the stay suture, which showed the black discoloration not only over its entire base but also in the depths of the suture tract. The edges of all were sharply defined with the slightest margin, possibly a line in thickness, of redness circumscribing the pustule. As stated, the infection did not extend beyond the gauze pad used as dressing and was definitely confined to this area. As a result of this observation, it was at once recognized that we had encountered an implantation of a species of mold fungus, most likely *Aspergillus niger*. There was no postoperative elevation of temperature nor any other untoward symptoms. Following exposure of the wound field to air and washing with iodine and alcohol, the apparent ulcers and pustules had entirely disappeared by the next morning, leaving dry, slightly scaly, areas outlined by a faint red line to show where they had been.

The history and the appearance is characteristic of three cases observed. The first was seen thirty years ago and the second about twelve years ago, each of them exhibiting similar pustulation confined absolutely to the area of the gauze dressing and healing rapidly after exposure and painting with 3 per cent tincture of iodine followed by alcohol and dressing applied so as not to exclude air. A photograph of the second case, which followed an emergency appendectomy, failed to show the details sufficiently to warrant publication.

At first the inclination was to construe the aspergillus found in these cases as truly pathogenic in character, but after consideration one may come to the conclusion that this is not true and that the condition can be called an infection only in the broadest use of the term. The explanation may be that following the preparation of the patient's skin there is in the operating room atmospheric contamination by this organism. It is sealed up by the dressing, skin reaction ensues, blebs are formed under the adhesive plaster or any other dressing that may be used, and the serum in these blebs furnishes a most desirable pabulum for the growth or there may be a bit of oozing from a stay suture stitch hole or from the lips of the wound, and such would act as an excellent culture medium.

Culture of other packages of dressings put up at the same time as those used in this case proved absolutely sterile, nor was there any evidence of any skin infection in any other clean case in which operation was performed the same day or on previous or subsequent days.

Of the 375 species of *Aspergillus*, 57 are pathogenic, and 40 are pathogenic for man. The majority of pathogenic species have been found in the ear. These organisms have also been found in the lungs, bronchi and throat about the nails in an ulcerated cornea and in the feces. The organisms were isolated from the beards of two Africans by Castellani.

Aspergillus niger A conidia B twenty four hour growth showing young mycelium C mature organism D cross section of conidiophore (c chains of conidia, ps primary sterigmata ss secondary sterigmata s stalk v vesicle)

The specimen sent to the laboratory consisted of the surgical dressings covered with a dark powder. This powder was planted on Sabouraud's maltose agar and potato. A rich growth was obtained on the agar in twenty-four hours and on the potato in seventy-two hours. Spores were then planted in Sabouraud's maltose agar between a coverslip and slide and the growth was followed under the microscope from a single spore to maturity. This microscopic slide culture method has been invaluable to us in the study of fungi.

The organism has been identified as one of the strains of *Aspergillus niger* but differs somewhat from any of the strains already described, as will be seen from the drawings. The characteristics of these organisms are as follows: colonies growing rapidly and becoming very black on the surface after several days, with abundant submerged mycelium, mycelium colorless, aerial hyphae scantily produced, globose, superficial conidia, stalks mostly arising directly from the substratum, some uncolored and some yellow to brown only near the vesicle, smooth, with walls thick and without pits but frequently uneven on the inner surface. The mycelium is septate, each hypha having a distinct nucleus. The vesicle is globose, thick walled and a yellow brown. The sterigmata are both primary and secondary.

From the Department of Surgery, Norton Memorial Infirmary
1 Myers J. T. and Dunn A. D. *Aspergillus* Infection of the
Hand J. A. M. A. 95:794 (Sept 13) 1930

Large numbers of calcium oxalate crystals were found in Sabouraud's maltose agar near the growing organisms. The disaccharide maltose is hydrolyzed by the enzyme maltase produced by this aspergillus and is broken down into two molecules of the monosaccharide dextrose

Citric acid is then fermented from the dextrose as an intermediate product

This reaction is not fully understood. Buchanan thinks that possibly the acid is synthesized from some of the decomposition products of the sugar.

Oxalic acid is formed from the citric acid. When the acid formed is neutralized by the addition of chalk, one half of the calculated theoretical yield is obtained.

This is an interesting phenomenon. The finding of large numbers of calcium oxalate crystals in the mediums may give one an immediate lead as to the type of organisms present.

REPORT OF CASES OF CARBON MONOXIDE POISONING TREATED BY METHYLENE BLUE INJECTION

A. W. CHRISTOPHERSON, M.D. HERMISTON, ORE

I wish to report further confirmative evidence of the value of methylene blue (methylthionine chloride U. S. P.) in the treatment of carbon monoxide poisoning.

Recently five men were brought to me for emergency treatment following a mysterious poisoning. They had been working with a road construction crew and were blasting rock in a tunnel measuring 6 by 10 by 115 feet. The blast was set at the depth of the tunnel and ten minutes later two of the men entered the tunnel to commence work. After a few moments one of them sensed the danger and warned the other to run. The latter collapsed almost immediately and the former ran but collapsed at the mouth of the tunnel where he was dragged to safety. One man ran into the tunnel and rescued the fallen man but he also collapsed when safely within reach of others. These three were rushed to the hospital, where I attended them.

Within thirty minutes two more men were brought to the hospital. One had entered the tunnel with an air hose to blow the tunnel clean and in a few minutes he collapsed. Another witness rushed in and placed the victim on a belt conveyor and both were brought to safety.

I immediately diagnosed the cases as carbon monoxide poisoning and put all to bed with high elevation of the foot of the bed, external heat, and pure oxygen inhalation. Three required caffeine sodobenzoate and two, atropine sulphate for cardiac and respiratory stimulation.

Two of the men were profoundly comatose and required artificial respiration as their voluntary respirations varied from three to five per minute. Their pulses were weak, rapid and irregular. Their color varied, the younger man, about 28 years of age and robust, was flushed pink from head to foot, the other, a man of 55 who had dissipated heavily, was cyanotic and in convulsions.

An attempt was made immediately to obtain ready prepared methylene blue, 1 per cent for intravenous injection, but as it was not available, a solution was prepared locally. An hour had elapsed when the solution was ready and as the two severely affected patients appeared unimproved they were both given 50 cc. of the solution. Before the injection was completed, they became conscious and talked rationally. Both made rapid, uneventful recoveries and, while more cautiously handled, seemed to have recuperated sooner than the three remaining patients.

The remaining cases responded promptly to the oxygen and the dye was not used. One of these patients later had the stormiest recovery of the lot and is the only one remaining under my care at this time, having a local systolic murmur over the heart apex, which may or may not be organic.

It would appear that the methylene blue had a remarkably specific action in these cases of carbon monoxide poisoning.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
PAUL NICHOLAS LEECH, Secretary

NAIODINE NOT ACCEPTABLE FOR N. N. R.

"Naïodine" is a product of the Emile Logeais Laboratories of Boulogne sur Seine, France, distributed in the United States by E. Tougera and Company. It is proposed for subcutaneous intramuscular or intravenous injection for the relief of pain from whatever cause.

The advertising material for Naïodine, widely promoted to the medical profession, is pernicious. Rarely today can one read claims of therapeutic usefulness more imaginative in conception or less supported by fact.

Naïodine is claimed to be a "one per cent solution of hyperactive sodium iodide (NaI) stabilized by a special process, exclusive of any other active principle, toxic or otherwise."

There is no chemical method known to the Council whereby a simple, highly ionizable salt like sodium iodide can be rendered "hyperactive," whatever that may mean. The implication in the advertising circulars that this iodide preparation is of a special order of therapeutic effectiveness is highly improbable. It is well known that the addition of small amounts of alkali, preservation in hard glass, and protection from light may tend to prevent the decomposition of iodide solutions.

The following are some of the claims made for this preparation:

"NAIODINE is indicated for the relief of pain and distress whatever the organ affected, whatever the site of pain and whatever the nature of the pain or distress present, whether it be due to neuralgia, neuritis, spasm, inflammation, sympathetic pain, anguish or anxiety [Italics ours]."

NAIODINE is as powerfully effective against the anguish accompanying the withdrawal treatment in cases of toxicomania as it is against the so-called essential sciatica, the crises of asthma, sinusalgia, the tarsalgia affecting adolescents, uterine or ovarian pain in dysmenorrheal patients, pain present in advanced cancer, myalgia, rheumatic or rheuma toid pain and the like.

In brief, NAIODINE constitutes a type of sedative preparation, a faithful antispasmodic and an analgesic. It may be added that the injection of NAIODINE is painless.

The sodium iodide present in NAIODINE when introduced parenterally possesses a veritable neurotropic effect. When absorbed by the capillaries it progressively impregnates the nerve centers, somewhat as bromides impregnate them, diminishes and suppresses promptly their sensitivity to pain. Large doses must be employed from the very first and must be repeated without hesitation. There is no reason whatever for hesitating since Naïodine is atoxic and since it produces no modification whatever of the respiratory or circulatory centers.

Injectable NAIODINE permits atoxic treatment of all algic states. It replaces morphine and other analgesics, all of which are toxic. Naïodine is atoxic and painless. Any dosage may be injected without the least difficulty. It has no contra-indications.

Use and dosage. The Treatment of Attack by massive doses 20 to 30 cc. daily given in one or several injections. Maintaining Treatment with diminishing dosage 10 to 5 cc. daily. Injections in any muscular mass, deep subcutaneous or intravenous.

Naïodine is further recommended for "sciaticas, lumbagos, shingles, trigeminal neuralgias, syphilitic and rheumatismal iritis, dyspnea, angina pectoris, asthma, pulmonary emphysema, toxicomanias, phlegmons, burns, acute arthritis, painful chronic arthritis, acute otitis, etc."

A brochure also is distributed, composed about a photograph of a woman's head in marble reproduction, at the bottom appears "Naïodine—cure atoxique," in one margin, "ne plus souffrir," repeated several times in type of diminishing size.

Naïodine is claimed to be absolutely atoxic, now here is there mention of the possibility of iodism, of anaphylactoid reactions from intravenous injection, or of the possibility of inducing serious or even fatal pulmonary edema in susceptible individuals, particularly in the pathologic pulmonary conditions for which Naïodine is recommended. The routine use of injections of sodium iodide to replace "morphine and other analgesics" as

advised in the advertising should be vigorously condemned. The advisability of parenteral administration of iodides in general is open to serious question, as these salts are readily absorbed from the intestinal tract. To the Council's knowledge, it has not been demonstrated that oral administration of adequate dosage is inferior to parenteral injection in producing all the known iodide effects (with the exception of the anaphylactoid response to intravenous injection). The claim for a 'neuronotropic' effect of sodium iodide gives the impression of pure confabulation, it is well known that administered iodide is not retained in appreciable quantities in nerve tissue.

The Council declared Naodine unacceptable for inclusion in New and Nonofficial Remedies, because it is an unscientific preparation of uncertain composition (rules 1, 2 and 10), for which unwarranted and fantastic therapeutic claims are made (rule 6), and because it is marketed under an objectionable proprietary name (rule 8)

VI-CRIS NOT ACCEPTABLE FOR N N R.

Vi-Cris is the uninforming proprietary name under which Vi-Cris, Inc., Detroit, markets a mixture proposed for use as an antiseptic on mucous or skin surfaces and stated to consist of 1 per cent each of gentian violet (later qualified as Crystal Violet 6BN) and Brilliant Green dissolved in a mixture of grain alcohol 35 per cent and water 65 per cent. The specifications for the composition of crystal violet 6BN as furnished by the manufacturers indicate the insoluble matter as 1.98 per cent and the ash as 4.68 per cent. Both of these values exceed the maximum permitted for gentian violet medicinal-N N R (1 per cent in each case). No statement of composition appears on the carton, on the label or in the advertising.

The proprietary name Vi-Cris cannot be recognized, since this preparation is a mixture of two well known dyes and in no respect presents a distinct improvement over similar preparations in use.

No data are furnished in support of the firm's claim of "Powerful Antiseptic Properties" for Vi-Cris except several unsupported quotations attributed to several unnamed dentists in an advertising circular, and a report from "National Pathological Laboratories, Inc.," of Detroit. This report purports to give the results of a comparison of the bactericidal properties of mercurochrome, acriflavine, picric acid, iodine and Vi-Cris. The concentrations of only two of these substances are furnished, 'sat. sol' for picric acid, and in the 'twenty-four hour test, 2 per cent for mercurochrome. The method employed is not stated. The organism used is said to have been *Staphylococcus aureus* and not the standard typhoid bacillus. Phenol coefficients are not expressed. This report is therefore meaningless, no satisfactory evidence of therapeutic usefulness is available to the referee.

The advertising material is objectionable. Two circulars and one carton submitted reveal the following: "During a recent epidemic of IMPETIGO, Vi-Cris was the most successful antiseptic application." Vi-Cris is further claimed to be of value in erysipelas infections of the lips and face (which it is stated 'spread rapidly' and "may reach the brain"), carbuncles, epidermophyton (for which it is said to be "cooling, soothing, penetrating"), endocervicitis, pus appendix, mouth and throat infections, cellulitis, chronic suppurating wounds and sinuses, Vincent's infection, pyorrhea alveolaris, and other conditions. It is stated that "Vi-Cris is superior to any single dye used alone", also that it is "First Choice" in either the medical or dental field of antiseptics.

On the carton Vi-Cris is said to be "A Perfect Family Antiseptic" (no less), to be good for, among other things, "Burns," "Insect Bite" and "Deep Seated Inflammations." "It soothes inflamed tissues and advances healing."

These unsupported, all encompassing claims require no further comment.

This mixture is similar to one which has already been considered by the Council, namely "Acriviolet" (J A M A 98 480 (Feb 6), 1932). Quotation is made from the Council's report on this preparation which is also applicable in the case of Vi-Cris: "there is no critical evidence of any

superiority of this mixture over gentian violet alone." The implication of superiority is therefore not warranted.

The Council declared Vi-Cris unacceptable for New and Nonofficial Remedies because it is a mixture of unscientific composition, undeclared on the label or in the advertising (rules 1, 2 and 10), because it is marketed under an uninforming, proprietary name (rule 8) with exaggerated and unwarranted claims (rule 6).

The foregoing statement of the Council's consideration of Vi-Cris was submitted to the firm Dec 28 1932. Mr N McKinstrie, president of the firm, replied (Feb 11, 1933) that the firm had undertaken the manufacture of Vi-Cris at the instigation of physicians who had found the use of this combination of dyes advantageous. The solution is said to have been in use for ten years, having been brought to this country by Dr W L Hackett, who obtained the formula from Dr Victor Bonney of Middlesex Hospital, London. Notwithstanding the criticisms of the Council, the firm expressed itself as still believing that "this solution is one of the greatest bactericides" and as being anxious and willing to market it in a strictly ethical manner. The firm asked the Council for assistance in selecting a suitable name and expressed a willingness to market the preparation in a plain bottle and carton with name and chemical formula only. The firm stated "There is a demand, we are going to meet this demand and there is no reason why we cannot do so ethically and with your approval."

A letter from Dr Hackett (Feb 8 1933) recites his experience with this preparation in Dr Bonney's clinic and states that in his experience 'the solution has been the most satisfactory bactericide in my possession.' A copy of a letter from Dr Bonney dated Jan 12, 1933, to Dr Hackett, forwarded to the Council's referee, recounts Dr Bonney's continued satisfaction in the solution as an antiseptic. Dr Hackett kindly loaned the Council's referee, through the secretary, a copy of the 1920 edition of 'A Textbook of Gynecological Surgery' by C Berkeley and Victor Bonney, in which on page 35 this solution and its uses are described. The referee has not located an article on this preparation said to have appeared in the *British Medical Journal* May 15, 1915. That article is said by Dr Bonney to contain the suggestion on which this preparation was developed. Neither the 'Textbook' nor any of these letters presents any data of controlled experiments. It is well known that both crystal violet and brilliant green are bacteriostatic for certain bacteria under certain conditions. It is known also that dentists and others make use of these dyes, singly or in combination, for antiseptic purposes. A letter from the secretary of the Council on Dental Therapeutics of the American Dental Association reports that a similar preparation is "in somewhat common use among dentists."

It is obvious that Vi-Cris cannot be made acceptable at this time. The marketing of the dyes as dyes would not involve the Council if no claims were made for their antiseptic action.

In view of the previous action of the Council with respect to Acriviolet, and in view of the fact that no new evidence has been supplied to establish the claims made for Vi-Cris, the Council voted to confirm its earlier decision that Vi-Cris is unacceptable for inclusion in New and Nonofficial Remedies.

TYRAMINE-ROCHE OMITTED FROM N N R.

Tyramine-Roche, a product of Hoffmann-LaRoche, Inc., Nutley, N J, was accepted in 1917 as a brand of tyramine hydrochloride-N N R, and has been reaccepted at the close of each acceptance period up to the close of 1932. At that time the Council's referee, in considering its eligibility for continued inclusion in New and Nonofficial Remedies, reported to the Council his conviction that the drug has not fulfilled the promise of usefulness under which it was accepted and has become of little or no therapeutic importance. The referee pointed out that the firm, for some years, has not submitted advertising for the product and is apparently making no effort to promote its sale.

The Council concurred with the referee's opinion concerning Tyramine-Roche and voted to omit it from New and Nonofficial Remedies.

Committee on Foods

GENERAL COMMITTEE DECISION

THE COMMITTEE ON FOODS AUTHORIZES THE PUBLICATION OF THE FOLLOWING GENERAL COMMITTEE DECISION ADOPTED FOR ITS OWN GUIDANCE AND FOR THAT OF FOOD MANUFACTURERS AND ADVERTISING AGENCIES ON FOOD COMPOSITION AND FOOD ADVERTISING

RAYMOND HERTWIG Secretary

GOOD FOOD ADVERTISING

Food advertising must be considered from the points of view of both the public and the food merchandiser. Sound advertising effectively serves the interests of both. The continued welfare of the food industry rests largely on the dedication of its advertising activities to the good of the public. It is essential therefore, to define proper food advertising.

Proper food advertising should use the common name of the food concerned or, in the case of a fanciful trade name, should identify the ingredients in the order of their decreasing proportions in the product. Such practice prevents deception. Any statement of the physical, chemical, nutritional or physiologic properties and values of the food should be truthful and expressed in simple common terms. Proper advertising is free from false implications. It does not create incorrect or improper inferences or comparisons between foods. It attempts to promote sales solely on the merits of the food article itself.

Good food advertising harmonizes with established authoritative knowledge popularly expressed. Meritorious foods require no exaggerated, false, misleading claims. The inferior food with alleged fictitious values requires gross superlatives and exaggerations, and flamboyant vague and mysterious claims. Good advertising discusses nutritional values but avoids specific health claims, it recognizes that health depends on the diet as a whole and on many factors other than foods and not on any one food brand or any one type of food.

REPORTS OF THE COMMITTEE

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

BETTY JANE FLOUR (PHOSPHATE ADDED)
(BLEACHED)

ROBIN'S BEST FLOUR (PHOSPHATE ADDED)
(BLEACHED)

Manufacturer—The Robinson Milling Company, Salina, Kan.

Description—Hard winter wheat 'standard patent' flours admixed with 0.5 per cent calcium acid phosphate, bleached.

Manufacture—Hard winter wheat is cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended, bleached with a mixture of benzoyl peroxide and calcium phosphate (one-half ounce per 196 pounds) and chlorine (three-fourths ounce per 196 pounds) and 0.5 per cent calcium acid phosphate is added.

Claims of Manufacturer—"Phosphated" flours for biscuit baking.

BABY RUTH CANDY

BABY RUTH BUDDIES CANDY

Manufacturer—The Curtiss Candy Company, Chicago

Description—Chocolate coated confection bars containing caramel dipped cores of fudge and roasted peanuts, prepared from peanuts, corn syrup, chocolate, sucrose condensed skim milk, coconut butter, salt, egg albumin, vanillin and coumarin.

Manufacture—The fudge center is prepared by boiling definite proportions of corn syrup, sucrose, skim milk, coconut butter,

salt, egg albumin and flavor, it is pumped into starch molds, which are mechanically emptied, and the centers are dipped into caramel. The caramel covered fudge centers are mechanically covered with roasted peanuts, after which they are mechanically enrobed with sweetened chocolate. The bars are cooled and wrapped.

S & H SLICED BREAD

SANITARY HOLSUM S & H BREAD

Manufacturer—S & H Baking Company, El Dorado, Kan.

Description—A white bread made by the sponge dough method (method described in THE JOURNAL, March 5, 1932, p. 817), prepared from flour, water, sucrose, sweetened condensed milk, lard, salt, yeast and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

MARTINELLI'S GOLD MEDAL SWEET PURE APPLE CIDER

Manufacturer—S. Martinelli and Company, Watsonville, Calif.

Description—Pasteurized sweet apple juice.

Manufacture—Sound, clean hand-picked ripe apples (Newton Pippins, Bell-Flowers, Permain and Missouri Pippins blended) obtained direct from farmers and apple packing plants are used, from the packing plants the grade is known as cider or drier apples, which are without stems, with skin blemishes due to rubbing in the trees, birds or insects, with sunburn spots or handling bruises, apples too small for packing or drying are used also.

The apples are rolled past inspectors, who discard badly bruised fruit showing signs of mold or rot, they are washed in an alkaline or acid solution to remove any arsenical spray (U. S. Dept. Agr. Bull. 1687), and are ground to a pulp, which is built up to a height of several feet in layers between heavy cotton cloths and wooden racks. The juice is expressed by pressure. The cotton cloths retain the coarse pomace, the juice is pumped continuously through a filter of tightly stretched canvas on frames of acid-resisting bronze. A filter aid of infusorial earth is used to facilitate filtration. Metallic contamination is avoided by the use of acid-resisting bronze equipment. The filtered juice is automatically bottled and sealed. The process from pressing to filling is continuous, no heat is applied. The bottled juice is pasteurized at 73 C. for thirty minutes.

The sealed cider keeps indefinitely. No sugar or preservatives are added.

Titrate acidity as malic acid	0.4

Arsenic (As₂O₃) (individual samples) 0.34, 0.40, 0.36

Calories—0.7 per gram 20 per ounce.

Vitamins—The method of manufacture is believed to be as highly protective of the natural vitamin values as are any cider manufacturing methods now in use. The pressing, filtration, bottling and pasteurization processes are continuous, only a short time elapses between the pressing of the pulp, and the bottling of the juice. The cider is not heated in the open but is pasteurized in hermetically sealed bottles.

Claims of Manufacturer—Pasteurized apple cider conforming to the United States Department of Agriculture definition and standard for "fruit juice", contains no preservative.

**P M C MILK SUGAR (LACTOSE), NON-CASEIN SOLUBLE
MILK PROTEIN MILK SALTS, INCLUDING CHLORIDES,
PHOSPHATES AND CITRATES OF POTASSIUM,
CALCIUM SODIUM AND MAGNESIUM**

Manufacturer—Protein Mineral Company, Inc., New York.

Description—Dried milk whey with added milk whey minerals, including lactose, non-casein milk protein and milk salts (chiefly chlorides, phosphates and citrates of potassium, calcium sodium and magnesium)

Manufacture—Liquid milk whey, a by-product of the manufacture of cheese, is filtered and the residual fat removed by centrifugation. The mineral content of the resultant whey is increased with precipitated minerals from a separate portion of whey obtained by the addition of sodium bicarbonate or ammonia solution to whey. The precipitate is washed with water to remove the alkali and added to the filtered defatted whey to the extent of 2 per cent. The resulting liquid mixture is dried at a low temperature, producing a white amorphous powder which is packed in bottles

**READY FOR USE BISCUIT MIX
(BLEACHED)**

Manufacturer—F B Chamberlain Company, St. Louis

Description—Self rising flour containing patent flour (bleached) hydrogenated cottonseed oil, powdered skim milk, sucrose sodium acid pyrophosphate, salt, sodium bicarbonate and calcium acid phosphate.

Manufacture—The ingredients are thoroughly mixed in a batch mixer and packed in cartons

Analysis (submitted by manufacturer) —

Calories—3.9 per gram 111 per ounce.

Claims of Manufacturer—For biscuit, waffles and cake baking. The keeping qualities have been thoroughly tested.

**CLAPP'S ORIGINAL BABY SOUP
(ADDED SALT)**

Manufacturer—Harold H. Clapp, Inc., Rochester, N. Y.

Description—Comminuted cooked soup stock prepared from potatoes, tomatoes, carrots, unpolished rice, cabbage, celery, meat broth, whole grain barley, salt, onions and water. The method of preparation is efficient for retention in high degree of the natural vitamins and minerals.

Manufacture—The potatoes, celery, cabbage, onions, rice and barley are carefully cleaned. The broth is prepared by heating sirloin butts in water. Purchased canned carrots and tomatoes are used.

The prepared raw material and the canned ingredients are heated in an atmosphere of water vapor in closed glass lined Pfaunder kettles. After a definite cooking period the material is flowed into a monel metal straining apparatus or pulper, which is flooded with steam to exclude air. The pulped mass is pumped into a glass lined storage kettle, from which it falls by gravity to a filling machine, where it is filled into washed

glass jars, which are sealed and are processed at a temperature of 116 C. for about one hour.

Vitamins—The method of preparation efficiently protects the natural vitamin values.

Claims of Manufacturer—For all table uses but especially intended for infants, children and convalescents and for special diets. Only warming is required for serving. The natural mineral and vitamin values are retained in high degree.

PARADISE SODA CRACKERS (SALTED)

Manufacturer—Paul Schulze Biscuit Company, Chicago

Description—Soda crackers prepared from flour, lard, malt extract, salt, baking soda, yeast and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

Manufacture—The sponge dough containing flour, water, lard, yeast and a yeast food is fermented for nineteen hours at 26 C., flour, malt extract, salt, water and soda are added to make a stiff dough, which is again fermented rolled into sheets, partially cut into crackers, sprinkled with salt and baked on oven shelves at 232-260 C. for four minutes. The sheets are broken into crackers, cooled and packed in wax-paper inserts in cartons.

CREAM OF RICE

(WITH SMALL PERCENTAGE OF POWDERED SKIM MILK)

Manufacturer—Cream of Rice Corporation, New York.

Description—Mixture of granulated polished rice with a small percentage of powdered skim milk.

Manufacture—Polished Louisiana rice and broken rice are ground, bolted and aspirated to remove flour. Rice of desired granulation is heated to destroy any possible insect infestation, mixed with a small percentage of skim milk powder and automatically packed in cartons.

Calories—3.6 per gram 102 per ounce.

Claims of Manufacturer—A quickly digested "smooth" cereal practically free from any indigestible roughage.

**LARABEE'S AIRY FAIRY SOFT WHEAT
PATENT FLOUR (BLEACHED
AND MATURED)
AIRY FAIRY CAKE FLOUR (BLEACHED
AND MATURED)**

Manufacturer—Larabee Flour Mills Company, of the Commander Larabee Corporation, Minneapolis

Description—A soft winter wheat "short patent" flour, bleached and matured respectively with a mixture of benzoyl peroxide with calcium phosphate (one-half ounce per barrel) and chlorine (three-fourths ounce per barrel).

Manufacture—See procedure described in *THE JOURNAL*, June 18, 1932, page 2210.

Claims of Manufacturer—For cake, biscuit, and pastry baking.

SATURDAY JUNE 24, 1933

THE MILWAUKEE SESSION

The annual session of the American Medical Association just held in Milwaukee aroused most favorable comment because of the exceeding smoothness of organization by the local committee in the handling of the convention affairs. Event succeeded event exactly on schedule without apparent extraordinary activity and to the immense satisfaction of every one who participated. Moreover, the hospitality of local physicians seemed to reach every convention visitor.

If the majority of visitors were asked to name the most striking feature of the convention they no doubt would choose the Scientific Exhibit. By a felicitous arrangement, the individual exhibits were for the most part correlated with the papers read in the various sections, except for special exhibits by various departments of the Association and others particularly planned by the Committee on Scientific Exhibit. Because of the practical and timely character of the exhibits shown, many of the exhibit spaces were crowded with visitors throughout the day. The Scientific Exhibit apparently constitutes one of the best types of direct graduate education available. Particularly interesting is the fact that several of the state societies are planning a similar arrangement on a smaller scale for the coming year, an evidence of the appreciation of this work by those who saw the exhibit function.

The opening meeting and the President's reception were delightfully arranged and attracted capacity audiences. The Woman's Auxiliary of the State Medical Society of Wisconsin and particularly of the Medical Society of Milwaukee County developed a program of entertainment which again met with numerous commendations. Almost a thousand women registered with the Auxiliary and there were perhaps an additional thousand who enjoyed the meetings, teas, luncheons and dinners without formally registering.

At the meetings of the House of Delegates, almost 160 delegates were in attendance. Topics of major interest to the medical profession that were discussed included the economics of medical service, changes in the nature of medical education, the certification of

specialists and the routine work of the American Medical Association. In its executive session the House of Delegates tabled a resolution of the Committee for the Investigation of Birth Control and unanimously adopted a resolution against the persecution of any human being because of race or religion.

Exhibitors in the technical exhibits were also warm in their approval of the usefulness of this annual session, many of them expressing delight in what seemed to be a turn upward in general business conditions as reflected by numerous orders for books, medical preparations and apparatus. The total registration, over 4,600, afforded opportunity to exhibitors to meet considerable numbers of physicians and to give them at first hand insight into some of the newer methods and technics available in medical practice.

A final word must be said relative to the remarkable performance of the weather man responsible for conditions in the state of Wisconsin. Just before the opening of the annual session he blasted the Middle West with a heat wave that will still be recalled by the oldest inhabitants a century hence. As the visitors and Delegates began to arrive he suddenly relented and during the entire period of the annual session moderate temperatures and salubrious breezes prevailed. The foliage in the gardens of Wisconsin blossomed profusely, cooling beverages were available in abundance, and as the editor of the society notes in the country newspapers are wont to say, a pleasant time was had by all.

CERVICOVAGINITIS OF GONOCOCCIC ORIGIN IN CHILDREN

Vaginitis in young girls is a medical, social, sanitary and economic problem. It is a constant source of concern in the care of female infants and children and of young women, in home and school, in camp and orphan asylum, in day nursery, hospital, college, swimming pool, office and places of business. Little research or centralization of information on the subject has been done. As a detached problem, the control of vaginitis has engaged the attention of the general practitioner, the pediatrician, the gynecologist and the bacteriologist.

Brunet and others¹ have studied the disease from clinical, bacteriologic and sociological points of view in a series of 332 young children referred because of vaginitis of supposed gonococcal origin. Two hundred and forty-one children were studied with relative completeness, including 175 in whom vaginal endoscopic examination was made. Most of the cases were in young children. The ages ranged from infants under a year to girls of 13 or 14, but a fourth of them were 2 years or younger, more than half were under 6 and only one child in eight was older than 9. On admission, 192, or 79 per cent, of the 241 patients were judged to have

¹ Brunet W. M. Tolle, Dora M. Scudder, Sara A. and Medcalf, Anne R. Cervicovaginitis of Gonococcal Origin in Children. Report of a Project of the Bellevue Yorkville Health Demonstration of New York City. *supp 1 Hosp. Soc. Service Mag.* 1933.

positive clinical gonococcal infection, 33, or 14 per cent, were grouped as suggestive, while 16, or 7 per cent, were considered normal clinically. In all, 233 cases, or 97 per cent, were judged to be positive or suggestive either by clinical observations or laboratory tests. Clinical and laboratory reports corresponded to a high degree, 85 out of 100 cases agreeing.

In this series, it was found difficult to trace the source of infection. The potential source of infection was ascertained in 113 of the 212 clinical cases considered in detail. In 104 cases, evidence of gonorrhea was found on examination in one or more members of the family. Of the seventy-six mothers examined, forty-six, or 60 per cent presented clinical and bacteriologic evidence of gonorrhea, the remaining mothers showed evidence of chronic leukorrhea. Only twelve of the fathers were examined, but of these nine were infected. While infection from contaminated articles such as towels, toilets and bathtubs, is by no means impossible, the majority of the cases studied resulted from close intimate personal contact within the home. Gonococcal cervicovaginitis in the children of this series was infrequently the result of sexual contact.

Cervicovaginitis in children does not differ widely from a similar infection in adults. Its course resembles that in adults. Smarting and frequent urination started in from three to eight days after infection, with a subacute or chronic stage soon developing. The difference from the adult picture lies in the rarity of inflammation of the vulvovaginal glands, the urethra, and the fallopian tubes and peritoneum. In only four cases of the series did pelvic involvement occur, and eye infection in but two, only one of which was gonococcal. Rectal involvement was rare, and arthritis was not observed.

Examination of the cervix, however, showed it to be infected in about four fifths of the cases. The clinical appearances in the positive cases ranged from a slight redness of the cervix to the large soft edematous type which bleeds easily when swabbed. Several patients had ectropion of the mucous membrane and a large number had a granular condition about the external os. No high degree of erosions was seen. There was a strong tendency to persistence of the inflammation.

Careful bacteriologic studies were made in 322 cases of the series. Of this number, only three cases showed gram-negative diplococci other than gonococci. However, the demonstration of typical biscuit shaped gram-negative diplococci in stained films of secretions from the genito-urinary tract gave only presumptive evidence of gonococcal infection. Cultures were found to be the most important method of checking up on cases of cervicovaginitis. Newly infected cases ran a typical course and gave positive smears and cultures for from eight to fourteen weeks. Cultures were of little value in the diagnosis of some of the chronic treated cases, but often unexpected results were obtained from cases that appeared clinically negative. Pathogenic organisms

such as streptococci were isolated from the genito-urinary secretions in some cases. Other organisms found occasionally were gram-negative bacilli, sarcinae, and Döderlein's bacilli. No true diphtheria bacilli were found. The application of fresh animal serum at the site of a probable gonococcal infection, namely, the cervix and urethra—as suggested by Pribram and Jonas² in 1928, was found to be a valuable aid as a provocative in the diagnosis of the early chronic cases in which cultures had become negative.

Treatment in this series did not abort the disease. Its course, as compared with eighty-four controls which had mere external genital cleaning, was somewhat shortened by instillation of mercurochrome in 2 per cent aqueous solution applied daily at home and by mercurochrome in gelatin applied through an endoscope at the clinic. Vaccines did not shorten the course in fifteen cases. The results seem to indicate that gonococcal cervicovaginitis in young girls is a self-limited infection and usually fades out within a few months.

This study shows the need of further diagnostic tests to differentiate in the last stages, the gonococcal from the nongonococcal forms of vaginitis, and also tests to detect latent uncured cases which may be the unrecognized carriers of gonococcal infection, and, lastly, tests for proof of cure. In brief, the study consequently should serve as an incentive to further work on vaginitis of children with a view to the development of better methods of prevention and treatment.

AN IMMUNOGENIC PARADOX

Investigations currently reported by Dr L. T. Webster¹ from the Rockefeller Institute indicate that selective breeding of animals resistant to one microbic disease may inadvertently produce animals hypersusceptible to other infections. The geneticists have pointed out many examples of similar "linkage" between hereditary functions. They would merely assume that hereditary microbic resistance involves a multiplicity of unit factors carried by different chromosomes. The observations have, however, immediate practical interest in their bearing on problems of animal husbandry.

Webster's studies were made on mice reared and maintained for nearly two decades under the most scrupulous hygienic conditions. During this time the herds of mice had never been exposed to microbic infections. The most painstaking examinations had failed to reveal "carrier" conditions. On routine exposure of these herds to standard doses of mouse typhoid bacillus, the mice showed on an average 37.4 per cent herd mortality. The general mouse population, therefore, was 37.4 per cent susceptible to *B. enteritidis* when tested with standard doses and under standard dietary and climatic conditions. By

² Pribram Ernst, and Jonas E. Proc. Soc. Exper. Biol. & Med. 25: 627 (May) 1928.

¹ Webster L. T. J. Exper. Med. 57: 793-819 (May) 1933.

selective breeding this population was segregated into two immunologically distinct mouse strains. The first, or susceptible, strain showed an 85 per cent herd mortality. The second, or resistant, strain showed but a 15 per cent *B. enteritidis* mortality. By twelve generations of brother-sister inbreeding even higher hypersusceptibles were produced, one inbred strain showing an 89 per cent and another a 97 per cent *B. enteritidis* susceptibility.

By hybridization of the susceptible and resistant mouse strains, Dr Webster found that the hereditary microbic resistance is not "sex linked" and tends to be transferred as a "dominant" genetic character. Thus 89 per cent susceptible males or females crossed with 15 per cent susceptibles gave progenies showing a 17.7 per cent susceptibility. Back-crossed with susceptibles, Dr Webster obtained a second generation progeny showing a 61.2 per cent herd susceptible. Back-crossed with resistants, the second generation susceptibility was 34.2 per cent. A comparison of all herds with respect to sex ratios, relative fertility and body weight showed that the hereditary *B. enteritidis* resistance is not appreciably correlated with bodily vigor. From this one might conclude that selective breeding of domestic animals for bodily vigor alone would not necessarily produce immunologically superior herds.

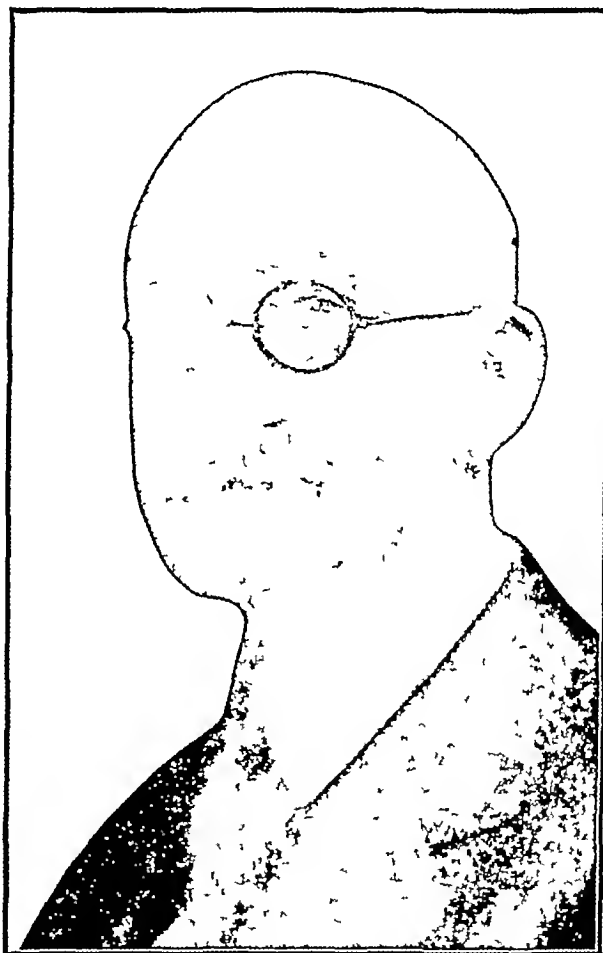

In order to throw light on the mechanism of this hereditary microbic resistance, comparison was made of the relative importance of hereditary portal defenses and inherited internal tissue resistance. This comparison showed that the resistant herds not only have more perfect superficial mechanical defenses to microbic invasion through the gastro-intestinal mucosa but that their internal tissues are also more resistant to direct subcutaneous, intraperitoneal and intravenous injection. These mice were also relatively resistant to nasal or pulmonary invasion by certain other infectious agents, such as *Pasteurella avicida*, Friedländer's bacillus and the pneumococcus. This resistance, however, was shown only when these agents were given intranasally

and not when injected directly into internal tissues. Dr Webster's paradox arises from his observation that hereditary resistance to *B. enteritidis* is apparently "linked" with hereditary hypersusceptibility to louping-ill virus.

Current Comment

WALTER L. BIERRING, PRESIDENT-ELECT

The election of Walter L. Bierring to the presidency of the American Medical Association comes to him as the culmination of a career of significance in medical organization. He has been awarded the presidency of the Iowa State Board of Health and the Iowa State Board of Medical Examiners (1914-1922), presidency of the National Board of Medical Examiners, presidency of his county and state medical societies, presidency of Alpha Omega Alpha, honorary medical fraternity, and a regency in the American College of Physicians. Dr Bierring was born in Davenport, Iowa, July 15, 1868, of Danish parentage, indeed, of the family which explored the northwest passage and the Bering Sea. He was educated in the schools of Davenport. He attended the State University of Iowa, in both arts and medicine, receiving his M.D. degree in 1892. His postgraduate study abroad included pathology and bacteriology in Heidelberg in 1892, in Vienna in 1892-1893, and in the Pasteur Institute of Paris in 1894. After his return from abroad he became professor of pathology and

WALTER L. BIERRING, M.D.
PRESIDENT-ELECT OF THE AMERICAN MEDICAL ASSOCIATION

bacteriology, and later of the theory and practice of medicine in the Iowa State University College of Medicine (1893-1910). From 1910 to 1914 he was professor of theory and practice of medicine in Drake University College of Medicine. From the earliest days of his career in medicine, Dr Bierring has been particularly interested in problems of medical education. He has served for some years as secretary-editor of the American Federation of State Examining Boards and was also a member of the Commission on Medical Education. He is well known as an internist. His practice has included the position of attending physician at the

Iowa Methodist, Iowa Lutheran and Mercy hospitals. In 1921 he was made an honorary member of the Royal College of Physicians of Edinburgh in recognition of his services in connection with medical licensure and reciprocity between Great Britain and the United States. Recently he was appointed state health commissioner of Iowa, which position he will assume, July 1. His contributions to medical literature have included articles particularly concerned with the heart and the circulation. He was secretary of the Section on Pathology and Physiology of the American Medical Association in 1905-1906 and chairman in 1907. He served also as chairman of the Section on Practice of Medicine in 1919. Dr. Bierring was a member of the House of Delegates, representing the Iowa State Medical Society, in 1904, 1905 and 1906, in 1910 and 1911 he was a member of the House as a delegate from the Section on Pathology and Physiology, and in 1922, 1923, 1924 and 1925 as a delegate from the Section on Practice of Medicine. In presenting Dr. Bierring to the House of Delegates, the delegates from Iowa called attention to the service which Dr. Bierring has rendered as a practitioner of medicine in contact with the people. In all his activities Dr. Bierring has recognized constantly the position of leadership which the American Medical Association must occupy as the only democratic representative of the medical profession in this country.

MATURATION HYPERSUSCEPTIBILITY

Recently THE JOURNAL commented on the spontaneous "serologic ripening" presumed to occur in growing children. It may be that this does not always function to their specific advantage, taking for instance the form of a "maturation hypersusceptibility" in place of the expected "maturation panimmunity." This possibility is suggested by Dr. E. L. Burky's¹ studies of the normal maturation cycle, made on rabbits, with staphylococcus filtrates as the test antigens. The selected filtrates were highly toxic for normal adult rabbits, intravenous injection of 0.25 cc per kilogram of body weight usually causing death within twenty-four hours. When these filtrates were injected intravenously into young rabbits, however, no symptoms were observed, even when the dose was increased to 2 cc per kilogram of body weight. This dose is at least eight times the usual adult minimum lethal dose. This toxin insusceptibility of young rabbits continues till about the fourth month, when the normal adult susceptibility begins to be demonstrable. One easily studied feature of this susceptibility is the parallel development of cutaneous allergy. Intracutaneous tests with highly toxic staphylococcus filtrates invariably give negative reactions in young rabbits until the approach of the fourth month. After this the local skin reactions are positive, as in the adult. Since the serum of nonreactive young rabbits will not passively immunize or "desensitize" adult rabbits to staphylococcus filtrates, Dr. Burky concludes that the nonreactivity of young rabbits is not due to an immunity in the ordinary sense. He postulates a "lack of a reacting mechanism at birth." This theory of an inherent

immunochemical deficiency is not original with Burky. It was suggested at least two years ago by Kobak and Pilot² of the University of Illinois, to explain a similar nonreactivity in infants. They found that, while about 95 per cent of all human mothers are skin reactive to *Staphylococcus aureus* vaccines, less than 2 per cent of their children under 2 months of age are reactive. The proportion increases to about 10 per cent by the fourth month and to 25 per cent by the eighth month, and approaches 70 per cent by the end of the first year. Whether or not this maturation cycle in infants and young rabbits is due to spontaneous physiologic changes or to environmental influences has not yet been tested. The work, however, is of basic interest, since it suggests the possibility of new interpretations of adult cutaneous sensitivity to numerous other toxic or infectious agents.

GROWTH VERSUS LONGEVITY

Modern nutrition is based on the intuitive belief that diets which produce optimal growth in young animals will also produce optimal health and prolong life. McCoy³ of Cornell University, however, holds that longevity and acceleration of growth are incompatible. Though not applying his conclusion to human medicine, he has no hesitation in applying it to veterinary science. Thus he writes that "the nutrition of animals that are to be slaughtered for meat shortly after they mature should be considered from the point of view of rapid growth. The same philosophy, [however, does not apply] to the rearing of dairy calves and horses [in which] it is desirable to have a long productive life span." The possibility of a physiologic incompatibility between accelerated growth and longevity was suggested more than fifteen years ago by Osborne and Mendel⁴ on the basis of nutritional data from rats. This suggestion was afterward confirmed by other investigators, using data obtained from nutritional studies with insects and brook trout. McCoy, however, draws his present conclusion from much more dramatic data, namely, a comparison of the average life span of modern laboratory-fed rats, with longevity records, twenty years ago, before rats had the benefit of modern research on vitamins. Twenty years ago, rats fed on the crude mixed diets of that period were reported to be of slow growth, many of them not reaching full adult size till the end of one year. Certain recorded groups of that time, maturing slowly, showed an average life span of more than three and one-half years. McCoy's rats of today, fed modern diets for accelerating nutrition, reach full adult size before the end of the first six months and live on an average for less than eighteen months. Slow growth and a short life span may result from certain dietary deficiencies. "No one has ever found it possible, however, [to devise a diet that will give] both rapid growth with early attainment of maturity and longevity." Whether or not this end could be obtained by two diets, a forcing diet during the growth period followed by more conservative nutrition during adult stages, has not yet been reported.

PROCEEDINGS OF THE MILWAUKEE SESSION

MINUTES OF THE EIGHTY-FOURTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT MILWAUKEE, JUNE 12 16, 1933

HOUSE OF DELEGATES

First Meeting—Monday Morning, June 12

The House of Delegates convened in the Grand Ball Room of the Schroeder Hotel and was called to order at 10 a m by the Speaker, Dr F C Warnshuis

Preliminary Report of the Reference Committee on Credentials

A preliminary report of the Reference Committee on Credentials was submitted by the chairman, Dr J D Brook, Michigan who reported that over one hundred delegates with proper credentials had registered and commended the promptness of the delegates in registering

The Speaker, not hearing any objections, declared that the list of delegates in the hands of the Reference Committee on Credentials would constitute the roll of the House for the first meeting

Adoption of Minutes of New Orleans Session

The Secretary stated that the minutes of the New Orleans session of the Association had been printed and put into the hands of all members of the House of Delegates and that no corrections or amendments had been received No objections being heard on the floor of the House the minutes were adopted as printed, on motion of Dr Charles E. Humiston, Illinois, seconded by Dr Arthur J Bedell, New York and carried

Owing to the death of Dr Albert E Bulson Vice Speaker, the Speaker appointed the Secretary, Dr Olin West, to act in this capacity temporarily

The Vice Speaker Dr Olin West, took the chair while the Speaker read his address which was referred to the Reference Committee on Reports of Officers

Address of the Speaker, Dr F C Warnshuis

Members of the House of Delegates

The thoughts and hopes of the medical profession of this nation are centered this week in this House of Delegates Every county and state medical organization appeals earnestly and hopes trustfully that your deliberations and enactments will formulate policies and procedures that will be helpful in their attaining solutions of the local and individual problems that confront them Every delegate should deeply sense his obligations and clearly recognize the magnitude of the trust that is reposed in him as a member of this House that must determine the policies of the Association That responsibility is greater today than during former sessions

This House is confronted by conditions created by epochal events in our national life They may necessitate revision of attitude and intensified activity with increased alertness as to how best to enhance the vital interests of the public and the profession

There is need for keen appraising judgment The greatest acumen must be subpoenaed in order that your final acts will well meet up to the demands of the times and continue to maintain the present high standards, functions and leadership of the Association Emotionalism must not supplant judgment The needs of the hour must not warp our vision or duty to the future Your Speaker is confident that you will respond to the need of the times by recording action that will reflect mature deliberation characterized by constructive, guiding enactments

It is desirable and essential that you secure every fact and obtain all possible information before final opinions are expressed To assist you in securing facts and accurate information there will be available to reference committees and delegates the Trustees and executives of the councils and bureaus of the Association and members of the headquarters personnel

Our Association's activities have many ramifications They intermesh in many of the Association's functions They are all interrelated and interdependent Consideration should be given to this fact before final action is taken on any question or when new programs are initiated

Your Speaker has been advised to emphasize this caution during this session, which is confronted with extraordinary problems Reference committees are advised to secure detailed information concerning Association affairs when they construct committee recommendations Delegates likewise would do well to confer with these sources of information before sponsoring a specific resolution or a motion dealing with Association policies Remember that however commendable your zeal may be and however soundly your arguments are constructed and applied to your own state, they may be of little value or aid when viewed in the light of what is or what will be most beneficial and applicable to a community, a state or the nation It would be prudent to reflect that local problems are best met by local action As a rule, they are not amenable to national enactments

Delegates who for the first time are representing their state organization are assured that active participation in the deliberations of this body is a duty that they owe to the profession they represent Every officer and member of this House will deem it a privilege to be of helpful assistance to you

It has been gratifying to observe the manner in which a goodly number of state delegations reported, in extended detail, the proceedings of the last annual session to their state organization Every state delegation should adopt this policy The members in your state should be thoroughly enlightened in regard to the actions and functions of their national association Characterize your service as a delegate by submitting a complete report to those whom you represent

COMMITTEES

Appointments to Reference Committees have been made to give nation-wide representation on a Fellowship basis It is recommended that delegates attend and participate in committee discussions By doing so you will expedite the work of this House

Your Speaker refrains from advancing specific recommendations I do, however, renew my expressions of deep appreciation for the honor of serving as your presiding officer To do so with every consideration for the rights of every delegate will be my steadfast purpose I am sincerely grateful for the trust reposed in me

DEATHS

And now, conforming to your instruction, it becomes my duty to call on you to pause to pay tribute to the memory of those who were of us but now are no more

They are gone from the mountain
They are lost to the forest.

In this hour of memory and tribute, I officially report the death of L E Broughton, Alabama, F C E Mattison, California, J S Helms, Florida, Albert E. Bulson, Indiana, J W Van Derslice, Illinois, T O Freeman, Illinois, J A Card, New York, E C S Tahaferro, Virginia, Frank Billings, Illinois, W S Thayer, Maryland, and A R Mitchell, Nebraska. These departed Fellows kept the faith and upheld

the honored traditions of their profession The now sacred memories that each bequeathed to us formulate our lasting tribute

Wherefore for us when real men die shall be no mournful graveyard glance Our souls with theirs invade the sky and to immortal strifes advance. For great is our inheritance when real men die

That inheritance to us is the memory of friendship endeared by their contributions for the joy happiness and fulness of all life for their fellow man 'Their sun of life has set as sets the morning star, which goes not down behind the darkened west but fades away in the glorious light of Heaven!'

They shall not be forgotten men!

This House will now stand in momentary silence to pay respect to all honorable members of the profession who have gone during the past year

Reference Committees

The Speaker resumed the chair and appointed the following reference committees

SECTIONS AND SECTION WORK

Isaac A. Aht, Chairman	Section on Pediatrics
J. W. Amesse	Colorado
E. F. Cody	Massachusetts
R. W. Fouts	Nebraska
J. N. Hunsberger	Pennsylvania

RULES AND ORDER OF BUSINESS

J. F. Hagerty, Chairman	New Jersey
D. E. Sullivan	New Hampshire
Horace J. Brown	Nevada
H. A. Gamble	Mississippi
M. L. Stevens	North Carolina

MEDICAL EDUCATION

Irvin Ahell, Chairman	Kentucky
E. D. Plass	Iowa
W. H. Ross	New York
S. P. Mengel	Pennsylvania
Mather Pfeifferberger	Illinois

LEGISLATION AND PUBLIC RELATIONS

C. E. Mongan, Chairman	Massachusetts
C. J. Whalen	Illinois
E. M. Pallette	California
Wells Teachnor, Sr	Ohio
A. A. Ross	Texas

HYGIENE AND PUBLIC HEALTH

W. F. Draper, Chairman	Virginia
J. C. Taylor	Wisconsin
G. C. Madill	New York
J. N. Henry	Pennsylvania
W. A. Cook	Oklahoma

AMENDMENTS TO CONSTITUTION AND BY LAWS

Holman Taylor, Chairman	Texas
Ben R. McClellan	Ohio

E. L. Skidmore	Utah
J. M. Birnie	Massachusetts

REPORTS OF OFFICERS

F. S. Crockett, Chairman	Indiana
C. T. Pigot	Montana
J. H. O'Shea	Washington
J. N. Vander Veer	New York
E. A. Hines	S. Carolina

REPORTS OF BOARD OF TRUSTEES AND SECRETARY

N. B. Van Eften, Chairman	New York
W. R. Molony	California
W. D. Chapman	Illinois
W. F. Braasch	Minnesota
H. H. Shoulders	Tennessee

CREDENTIALS

J. D. Brook, Chairman	Michigan
D. A. Rhinehart	Arkansas
W. H. Myers	Georgia
C. R. Scott	Idaho
H. A. Miller	New Mexico

MISCELLANEOUS BUSINESS

H. M. Johnson, Chairman	Minnesota
George Blumer	Connecticut
J. F. Hassig	Kansas
B. L. Bryant	Maine
A. R. McComas	Missouri

MEDICAL ECONOMICS

The Speaker, on motion of Dr. Arthur J. Bedell, New York, seconded by Dr. C. S. Gorshine, Michigan, authorizing him to do so, appointed the following reference committee on Medical Economics

A. J. Bedell, Chairman	New York
W. F. Donaldson	Pennsylvania
C. W. Waggoner	Ohio
Dudley Smith	California
Jabez N. Jackson	Missouri

Address of President Edward H. Cary

The Speaker, in presenting the President, Dr. Edward H. Cary, Dallas, Texas, said

It is a high honor to be President of our Association. In turn our Association is honored by its President. Few delegates realize and very few Fellows appreciate the tremendous contribution that is made to our Association by our Presidents.

We have been passing through troublesome times. Even after event has presented itself demanding action in order that our Association's interests be conserved, our policies sustained and our future enhanced. We have indeed been fortunate in having as our President one who was peculiarly fitted and exceptionally capable to meet the exceeding heavy demands that devolved upon him. Dr. Cary has responded in a most commendable manner. He has made a contribution that I do not believe has ever been equaled by a President of this Association. During his term of office he has traveled 99,190 miles on official business. He has been away from his home over 340 days almost an entire year, in keeping 80 engagements in which he was the Association's official representative—a wonderful record of faithful service.

It is my privilege and pleasure to present to you one who has served so well your President Dr. E. H. Cary.

Dr. Cary thereupon delivered the following address which was referred to the Reference Committee on Reports of Officers.

Mr. Speaker and Members of the House of Delegates

I come to you today with sincere appreciation of the opportunity which you have given me to serve the medical profession of this country and possibly the people. Unfortunately, conflicting engagements prevented me from accepting some of your invitations, but I have traveled widely and spoken numerous times, striving always to be worthy of your high trust. From these contacts on many happy and auspicious occasions I have gained inspirations, friendships and delightful memories, which I shall always treasure.

Concurrently with my occupation of this august office has occurred the worst period of this era of depression. There has been great restlessness among the members of our profession, some of whom were ready to adopt new methods of practice or become attached to untried schemes which might offer quick monetary returns. Only the force of medical opinion, grounded in ethical traditions and reaffirmed here and there could steady this distressed doctor until the economic situation changed or until reasonable adjustments could be projected and presented for discussion. Fortunately the tide has turned, and there is time for due consideration of the future economic and ethical relations of the profession to the public.

Your official family, whether its members are devoting all or part of their time to the business of our organization, have faithfully attempted to interpret the demands of the hour and have cooperated to sustain the high purposes for which the American Medical Association came into being. Contacts of very wide scope have been made. Old ties have been reinforced so that the policies of the organization have won favor and been generally adopted.

May I call your attention to a few of the outstanding policies carried to a successful issue.

First, the contention of our profession that the American physician should have the right to use his own judgment in prescribing alcoholic liquors. This principle has been accepted by Congress and a law passed which seems desirable to the members of our profession who have been interested in destroying restrictive legislation. The question of prescribing whisky for therapeutic purposes is placed on a basis on which medical men are to be trusted and, to maintain the high standards and dignity of our profession they cannot be other than worthy of this trust.

Second the contention of the profession that a federal law which affects the practice of medicine is undesirable when it is directed by a bureau under lay control from the seat of the national government, for example, the Sheppard-Towner Act. All activities of this character regardless of their humanitarian purposes, should be the result of the combined influence of the profession and interested citizens who advocate such services in their own states. The sentiment can be developed and the purposes of such measures made more effective if they have gained

the support of the profession without enlarging the possibility of national paternalistic legislation. We believe, that through the state public health service and the intelligent use of their responsibility the people will support such activities which are needed to meet the demands for a better care of the mothers and babies of the many commonwealths.

Third, we recognize that the narcotic question is international in aspect and will require further international agreement before it can be controlled. Narcotic legislation has received most careful consideration, and an enlightened policy has been followed. The Uniform States Narcotic Act had its origin from the work of one of your committees, created in 1919. Of course, much work has been done in conferences with other groups. Some of the states have already passed the act, and no doubt others will rapidly follow. It has been found that the federal law, however valuable, fails to meet effectively the local situation.

Fourth, your legislative committee has labored earnestly to meet the issue raised by the ever growing service to the veterans which is the result of legislation in their interest. The question of hospitalization has been a serious one and, though there has been no desire to prevent the most liberal care on the part of the government for the service-connected disabilities due to the war, we have strenuously objected to the liberalization of laws which permit the man who is able to pay for medical service to enter veterans' hospitals for free medical care. We have objected to more hospitals being built unless they are needed to care for those suffering with tuberculosis or with mental and nervous disorders, or unless they are needed as old soldiers' homes.

Your President with Dr. Woodward appeared before the joint committee of the Senate and House. The opportunity was accorded us to present what we believed to be your point of view on this question. The committee manifested an increasing interest in our presentation. Many questions were asked and we both felt that the committee agreed in the main to the principles we supported. Undoubtedly, a widespread sentiment has been developed in Congress that our government has gone far enough in its hospitalization program. We believe that the status of this question is in harmony with your views. Since the advent of the new administration, we have been told that no more hospitals are to be built even though the money has been appropriated, that some of the hospitals already built are to be closed, and that hospitals in process of construction and considered desirable will be finished and used. We were informed that the beds occupied by non-service-disabled veterans will be gradually assigned to those who are suffering with tuberculosis or nervous and mental diseases, while some of the hospitals are to be altered so that they can be used more and more for domiciliary care.

Following the adoption of the economy program of the President as to veterans' gratuities, an order was issued to the medical officers of the veterans' hospitals by General Hines, humane in tenor, stating that only those who were well or those who could be properly discharged from the hospitals be sent home. This order has resulted in about fifteen thousand patients being dismissed up to June 3, 1933. This is reflected in the cancellation of certain contracts with the army and the navy and in the reduction of personnel, physicians, nurses and other help in many of the hospitals which remain open. There has been an effort made to reduce the occupancy of all beds heretofore used by the non-service-connected disabled soldier and, when this point has been reached, then the future use of the beds will come from a very numerous group of service-connected cases, many of which are now being cared for at home. In other words, the department intends to keep the present beds, totaling 41,000, in veterans' hospitals in service. The rebellion of the Senate and House, forcing a compromise may reopen many phases of the question.

We must not lose sight of the fact that the present program is also the result of a depleted treasury and, if the economic situation of the country should improve before the present policy is well established the demands of the veterans having non-service-connected disabilities may reestablish abuses of governmental aid to which we have objected. Hence, it is necessary for members of our profession to continue their opposition, otherwise, we shall be confronted with the same situation as it

existed before Congress gave its support to the request of the courageous President of our country.

Fifth, the Report of the Committee on the Costs of Medical Care has stimulated the interest of the public and of the profession.

The Minority Report of this committee has been supported by the members of your official family and though both the Majority and Minority reports have been given wide circulation and thoroughly discussed, we feel that the great majority of the members of the medical profession throughout this country is supporting the Minority Report, both as to principles enunciated and as to the expediency of not determining a far-reaching policy affecting the medical profession at a time when the economic status of this country is abnormally low and likely to improve.

While cognizant of the demands made on the profession to readjust its methods and practices, we have protested that readjustments, if needed, should follow a full and complete discussion of all phases of the subject. We have believed that a solution can be found, through the cooperation of medical men who are deeply interested, that will not involve the destruction of fundamental values underlying medical practice. With this in view, the county medical societies have been encouraged to give serious study to the economic phases of the practice of medicine and to solve their problems, keeping in mind the fundamental principles underlying our ethical relations to one another and to the public.

We recognize the varying conditions and realize the impossibility of meeting this difficult situation with any one plan such as those that have been offered from various sources. Our organization is striving through its leaders at headquarters and elsewhere to serve the public and the profession of medicine, first by discussion of problems, secondly, by trial of suggested plans, thirdly, by searching for and finding the truth, and thus be able to crystallize the professional mind so that unity will prevail. We all recognize that until there is unity of spirit and professional desire among the members of the county medical societies which are units of our organization, no plan, however far reaching and humanitarian in its aspects, can hope to live without the cooperation of the majority of men practicing in that locality.

The desideratum to be ever kept in mind and preserved is the right of the patient to choose his physician. A free road or pathway should be kept open from physician to patient. Hospital budgeting plans should never include medical services. The two services should be kept separate and distinct.

THE RELATION OF THE PRIVATE PHYSICIAN TO THE HEALTH DEPARTMENT

On this subject of vital importance to the people and to the profession permit me to repeat a few comments I have made to public health men.

The relation of the private practitioner to the health department is sometimes made uncertain from the things he reads, the fundamental reason for his support may be there, but some one has raised, through statements or innuendo, doubt and fear as to the future of medicine. Organized medicine has come thus far because of its devotion to education used in its broadest sense. It has directed the forces which have made possible the educational enterprises which give to the service of the people, the highly trained medical men of our time. Organized medicine has at the same time, through its machinery given support, aid and comfort to campaigns which might advance the health forces of the nation. I think we can generally hold to the view that men who have charge of the health of the nation should have had the education and environment to make of public health servants experienced doctors.

An undergraduate medical school's function is to create doctors and not specialists, but I dare say every graduate of our class A medical schools has sufficient basic and general knowledge to acquire special knowledge readily by following that routine to which he is directed. This routine takes the graduate into practice with many experiences and to special places for intensive study, finally to be equipped to commence work in the chosen field, there to learn how to make useful his information gained through honest toil under happy circumstances.

We are deeply interested in the people having the benefit of all the knowledge necessary to protect them from disease, whether it be epidemic or among individuals in our immediate

care, and we agree, when a community is without the protection which comes from a well organized health program, that it is undoubtedly a mistake which may develop into a catastrophe.

Organized medicine as a whole is not willing to assume the errors of judgment or lack of medical leadership which prevails in any community where intelligent cooperative helpfulness toward public health is lacking, therefore organized medicine has a duty to perform.

Ferrell stated in an article in *THE JOURNAL*, May 6, that there are 967 cities in the United States with 10,000 inhabitants or over. Of these, 416 (43 per cent) employ full time health officers, of whom 265 (64 per cent) are physicians and 151 (36 per cent) are not. The 151 lay health officers are serving in twenty-five states. Forty-one of them are distributed in twenty-two states, and 110, or 73 per cent, are serving in the three states of Massachusetts, New Jersey and Pennsylvania. In these three states there are 220 cities of 10,000 inhabitants or over, of which 126 have full time health officers, of whom sixteen, or 13 per cent, are physicians, and 110, or 87 per cent, are not physicians. There are about 110 cities in the same states without full time health officers. He also states that there is a failure to provide medical leadership in health work in other states. We note that the nonmedical health officers are distributed in twenty-five states. There is evidently a lack of medical leadership in many where such a condition exists. It is of supreme importance that a clearer understanding of the responsibilities assumed by both the profession and the health officers should be so defined that organized medicine would more effectively support a program in which a complete agreement of an enlarged service of preventive and medical character would be made workable in the states which compose this great nation.

It would seem necessary to find a formula which would be readily accepted by those doctors who are engaged in private practice and by public health workers whereby the people would provide welfare budgets to compensate not only the health officer but the physician. These forces would then find a common ground in the support of a health department which contemplated the use of physicians who would more definitely render the needed service in an enlarged program of education in preventive and personal care of the health needs of the community.

It has often been said that the people have already been educated to believe in the efficiency of preventive measures, they subscribe to the theory that immunization is a demonstrable success. They know that epidemics can be modified or prevented through the activity of a well organized health department cooperating with a willing medical profession.

The leaders of three important forces are already educated to the value of applying the knowledge which is available for conserving the health of the people and controlling incidents of disease. These three forces are in a position to act, provided they are worthy of their responsibilities.

First, the public health officer whose knowledge and sincerity are known to the medical profession and the public. This would suggest that being a public health officer carries with it far more than political preferment, that he has won his place through education, adaptation and zeal, and a broad conception of human relations with a political prescience which, in itself, makes him unusual among his fellows. Necessarily, to gain the complete confidence of one of the vital forces, the members of the medical profession, it would be less difficult for the public health officer if his fundamental training is that of the physician.

The second force which can be found in every community is the broadly educated, far seeing medical practitioner, who believes firmly in the beneficent application of the applied sciences and subscribes to a doctrine which in itself, leads to a broader need of medical service from the practitioner. Without undue thought he realizes that the health, happiness and prosperity of the people of a community are a trinity of social significance on which future medical service may emanate and for which the medical man is repaid for his contribution to the common welfare. Service to living people extends to the grave. Longevity has its rewards in multiplied services needed from the medical profession. To serve people who suffer from disease and who are in despair offers emotional satisfaction to physicians for to help without thought of material reward has given deep gratification to members of a great profession whose thoughts are of others and not of themselves. How much wiser

and more beneficent, however, to combine our knowledge and influence to prevent disease and despair, finding elation from concerted action with an improved economic situation for all concerned.

The third force is enlightened public opinion. The people, ever optimistic and sometimes overcredulous, believe in the wonders of science. They have been so impressed with what has been accomplished in the prevention and cure of disease that they are impatiently seeking all the values to be had, anticipating the practical application of experiments before they are proved.

Among these three forces will be found the leaders who can be merged into a composite fighting battalion to mold their own kind into an effective unit for the common good. Leaders of each group must first stamp out suspicion and parallel high service with human needs not losing sight of the underlying economic situation, for lasting results depend on economic satisfaction.

The attitude of society should be directed to its own responsibilities. It should either correct the causes leading to dependence or assume its burdens as related to the sick so that this demand on the profession is cared for by society and not expected from the doctors. This should be accomplished through the use of the members of the county medical society and the local health agency. It is essential to cultivate public opinion to develop an adjusted budget by the various communities to meet their local health requirements.

Indigence should not be encouraged but should be recognized as a part of the social deficiencies which are to be met from a general fund rather than the present plan, which lacks the advantage of a definite responsibility. It is undoubtedly to the advantage of society as well as to the indigents to establish more concretely the forces that lead to the best remedial care. When attempting to construct a plan in one's own mind, which might aid in the solution of the difficulties which arise to separate these three groups, we must consider the strength of these forces, which through training and experience are to cooperate. Their respective influence on their associates and society is important. With this in mind, we evidently turn to the most logical group whose purposes and ideals definitely harmonize and whose machinery is best adapted to make it the one great power which can be used for the common good.

My friends, wherein does this power lie? Is it not in and through organized medicine? Has not the health and happiness of the people always been dear to the men who have made and who sustain the American Medical Association?

A great community interest encourages the individual doctor and sharpens the competition for him because the people are free to choose the men who can retain and best use the information acquired. This is made possible for all the people because of the activity and orderly force created and kept alive by organized medicine.

We believe that the conduct of the Association is well worthy of your approval, for it has not lost a significant point in policy or legislation in the last five years. Whatever success we have attained can be in large part attributed to the loyalty of the rank and file of intelligent men who keep abreast of the complexities of the day, whether the problem is scientific, social or legislative in character. These loyal men realize that the medical profession can consciously determine its own destiny, for, after all who can take the place of the medical men? We believe that we know how to educate and make useful the men in our profession. We realize that the restraint needed to curb the overambitious comes from within the profession. We know human nature. Medical practice has raised certain safeguards for the good of the practitioner and the patient.

In this connection, *THE JOURNAL* is the greatest means we have for distributing quickly information, without it we should be helpless in quickly mobilizing professional opinion. Although it is true there are many members of the American Medical Association who do not take *THE JOURNAL*—and let it be said here that they are appreciated members through their county medical societies—yet it must be clear that only through subscribing to the greatest medical periodical on earth do they become contributing members. No other journal of national interest in any other land can be had for the price paid for *THE JOURNAL*. A reduction in the subscription price, if only one dollar a year, would, the past year, have converted a net

gun of the Association into a probable loss, thereby curtailing many of the valuable activities of the organization. Our organization cannot safely retrench at this point, for *THE JOURNAL* is worth more than it costs in money and the money is needed and used in the interest of its members, after all, it was the income on our reserve some \$76,000, which has made it possible to proceed so confidently.

I am glad to state that your Board of Trustees will be able to report that during these trying times and in the face of the greatest period of expansion of the activities of our organization the economies established have made it possible to carry on efficiently without impairing the reserve fund which has been so consistently developed and which must be maintained.

We may congratulate ourselves on the appreciation the public has shown through its acceptance of *HYGIEA*, which has been self supporting and will increase in circulation with improved business conditions.

Undoubtedly the control of newspaper publicity as to medical matters has been in the interest of the public and the means of eliminating much misinformation. It reflects credit of an unusual order on the talent and perspicacity of the editor of *THE JOURNAL*.

The Committee on Foods is developing contacts and generating influences which will be far reaching because the people of this country are becoming more and more interested in the endorsement of this committee which is given only when spurious claims are eliminated from the advertisements of manufacturers of foods.

Let us not forget the necessity for a new building, as soon as the times become propitious. Our new departments of Medical Economics the *Quarterly Cumulative Index Medicus* the Bureau of Exhibits the Committee on Foods are being developed and require larger space. The services of our library have met with tremendous demands from members of our organization. We can extend these services with increased space and personnel. We should look forward to the accumulation of a great library of books which now we do not have.

Your President has realized the necessity for delay and has not advocated the development of plans for the needed new building for it has seemed wiser to conserve our resources and not expand at this time of world-wide distress.

In a similar manner, addresses and communications from bureaus and councils should be given to the public, creating a better understanding of the purposes and desires of organized medicine to be of service to humanity.

We have gone far in this direction and have reached a high place in human relations, we cannot be static for fear of retrogression. With the loyalty and support of our membership we can go further.

Loyalty is essential throughout the organization. Our leaders should have unquestioned ability and at all times be able to express wholeheartedly the views which represent the will and crystallized opinion of the vast membership which composes this body.

Though scientific groups for special study may continue to exist within the organization they should not promote individual views on economic topics and policies divergent from those of the profession as a whole. These policies are formulated in this House and become the act of constituted authority, your honorable body speaks for the American Medical Association.

For this reason your Board of Trustees is composed of representative men who are and must be in sympathy with and interpret your wishes. They assume the responsibilities you have placed in their hands and wisely serve the entire membership of our organization, which is represented by this House of Delegates.

There will be many resolutions presented for your consideration. If the wisdom displayed in the previous sessions of the House prevails and there is no reason to doubt this, American medicine has nothing to fear.

Those states which have so wisely returned their delegates year after year protect medicine from the vagaries of the hour. Seasoned legislators are not created in a day. It has required patriotism and a very deep interest in things which concern the welfare of medicine to bring you annually to these meetings regardless of the meeting place and the distance you must travel for such occasions. To you and to your earnestness, I bend

my knee. I only wish that the medical men of this country could understand you as I do. You would have in many places a finer sense of obligation developed toward you.

While it is not necessary to remind you of the absent ones, I cannot forget that some of the staunch defenders of the faith are absent from this House. When I think of the elder statesmen who have been in this House so many years, I feel that I am treading on holy ground for I have had a personal loss in the passing of the great medical statesman Frank Billings, the faithful trustee A. R. Mitchell, the strong and responsive Vice Speaker and erudite Editor Albert E. Bulson, and the courageous and lovable J. W. Vanderslice, and others whom I did not have the pleasure of knowing so intimately. The older members of the House will, I am sure, feel the same sentiment. May we all emulate their nobility.

Again I wish to express my gratitude for your preferment. You have helped to create pictures of your friendliness and trust in my memory which I shall never forget, bringing pleasure and keen satisfaction in the opportunities I have had to serve you.

Address of President-Elect Dean Lewis

The Speaker, in presenting the President-Elect, Dr. Dean Lewis, Baltimore, said:

Your Speaker feels that the man you elected to succeed Dr. Cary as President at the close of this session possesses all the qualifications that that office exacts. He is an experienced, tried traveler; he is a bedside surgeon, intimately familiar with the practice problems of physicians. He is a student of economics and is endowed with keen discernment. He has our respect and confidence. We may safely rely on his sound leadership. Gentlemen, President-Elect Dean Lewis.

Dr. Lewis thereupon delivered the following address, which was referred to the Reference Committee on Reports of Officers.

Mr. Speaker and Members of the House of Delegates

Physicians have suffered acutely during the depression and have rendered their services freely without complaint. Apparently during periods of depression the morbidity and mortality are less than during periods of prosperity and inflation. I am told that insurance companies have known this for years and their statistics verify the foregoing statement. We are now apparently suffering the economic consequences of peace.

One of the main problems which had a decided effect on the profession was the extensive hospitalization program which the government embarked on immediately following the war. The legislation that was passed is of such recent date that it is not necessary to review it. Non-service connected disabilities entered largely into the program, so that finally almost 70 per cent of the cases that were hospitalized presented disabilities which had nothing to do with the service and did not even have a presumptive connection. Ochronosis, acidosis, gout and obesity were even on the list of diseases and were applied in the rating of disabilities. In the economy program that has been attempted non-service-connected disabilities were excluded. Recent happenings indicate that much pressure has been brought to bear and that hospitalization of non-service-connected disabilities may again be attempted. If the bars are let down there will gradually be an increase in the amount of hospitalization and a return to the conditions which existed before the attempt to economize was made.

There is no argument as to the responsibility of the government in the care of the service-connected disability, nor as to the responsibility of the government to the widows and orphans of those who were sacrificed in battle. But any man discharged from the army who is able to make his living has no lien on the government. This is generally admitted. It is much more difficult to rescind legislation than it is to prevent its passage. The medical profession must still make untiring and unceasing effort to prevent the hospitalization of non-service-connected disabilities. If such continues the foundation of medicine and the future of medicine are threatened. Hospitals already built for the care of the civilians in different parts of the country cannot carry the financial load long. I realize that not infrequently the medical profession has a bad press and that they are regarded as selfish. Any suggestions which they may make

are suspected of being based on some ulterior motive. The history and traditions of the profession refute such statements. Continued effort should be maintained to prevent a return to the system which prevailed before the economy act was considered. Personal contact with legislators is about the only method we have to prevent the continuation of a scheme which will bankrupt a government and if bankrupt, even the non-service-connected disability will have nothing. We will all be in the same boat, which is disabled and tossed about.

There may have been some injustices, but these could be corrected. It may be difficult for legislators to realize that it is frequently impossible for a physician to say that a disability was connected with service. This applies especially to a disease such as thrombo angitis obliterans, a number of cases of which are coming up for consideration. Whether these developed while the patient was in the service cannot be determined with certainty.

The different reports which have been made from time to time relating to medical care have been discussed so frequently that it is doubtful whether anything should be said about them. We all know that there are defects in medical practice. There are no systems of practice that are without fault. We have heard too much about the costs and about the distributions of the cost and not enough about the quality. Some of the criticism has come from those engaged in business who have promoted instalment buying and have encouraged people to assume obligations which are so great that those dispensing the necessities of life have had payments long deferred and, at times, no payment has been made at all.

The losses which hospitals have suffered led them to accept different schemes, which they will be glad to cast off when the depression is over. You will hear that it has been found after a careful survey that there are more than thirty schemes which have been proposed to provide for the periodic prepayment purchase of hospital care. Some of these schemes are revolutionary in character. They are proposed and backed by propagandists and promoters who are looking for a profit. Beware of the promoters who are robbed in the pure white of charity. No consideration is given to the relation between patient and physician. They have not confined their effort to the low income groups, and no attempt has been made to exclude from their scheme the final inclusive medical service with hospital care. In fact, in some of these schemes it is frankly stated that such is the ultimate aim.

It has been stated and no denial has been made that under any of the schemes which have been proposed to bring forth a medical Utopia suddenly that the mortality has not been decreased and the length of sojourn in the hospital has been doubled. The length of stay in the hospital is in marked contrast to the present system, in which an attempt is made to return the patient to life as soon as possible with as little disability as is compatible with his sickness or injury. Hospitalization for minor illnesses has increased and malingering has become a part of the system. It is natural for a man to get some return for his money, and he will seek under such a system hospitalization to secure some return from money invested.

It has been the history of all these movements that voluntary insurance is unsuccessful, and the compulsory insurance is finally adopted.

One of the founders of a foundation which gave financial support to Committee on the Costs of Medical Care has recently made the statement that voluntary insurance is not successful and that compulsory insurance should be put in effect as soon as possible and that this type of insurance should be placed for consideration before the federal authorities.

Judging by the performance of the business world during the past two years I should say that the medical profession has shown more ability to take care of its own business than any other profession. Physicians make mistakes but their practice has been on a high plane and will continue on this plane if cooperation is practiced instead of competition and if bidding for practice does not replace the system which has been in vogue since the beginning of practice.

Questionable practices regarding fees must be settled by the profession not by legislation but by developing a profession

which places service above financial gain and give to each patient a square deal. Some will say that such a statement is superidealistic, perhaps pure piffle, but during the past few years we have seen a distinct improvement in the tone of medical practice and I believe that this will continue. There will probably always be some sharp practice. There will be some sharp practice in all professions. When it ceases we shall be translated and all the schemes suggested at the present time will pass away. The only one left to inhabit the earth at that time will be the paid secretary, promoter or propagandist, and they will be so lonesome that they will pray to be speedily destroyed.

The medical profession should take an active interest in hospitalization. Hospital planning should be undertaken. A city or town of 15,000 people should not have three hospitals. One good hospital could take care of the needs of such a community. Better have one hospital that is full and active than three partially filled. The partially filled hospital has an enormous overhead. Always expecting to be filled, it keeps a large civilian staff always expecting that it will suddenly be called on to work overtime.

Hospital construction has run riot. Many hospitals are built as memorials, and some are built to tickle the vanity of hospital architects. This point has been emphasized so much that I need say nothing. One of the many increases in the cost of medical care has been hospitalization.

In some ways the depression has rendered a great service, as it has been demonstrated that many of the mechanical aids to practice are not necessary and that the cost of medical service may be greatly reduced and the quality maintained. Sir James Mackenzie stated the case well when he said "It would be ridiculous to put a man with a cut finger through such a process [a thorough examination] and expect him to pay for it, as it would be to expect an automobile owner to have the entire machine overhauled each time he has a puncture." Simplification of medical practice should be the aim of this organization. Such a simplification will mean a limitation of specialism and the reduction of specialists. A motion providing for the recognition and listing of specialists was passed last February before the Council on Medical Education and Hospitals.

When medical education was passing through such revolutionary changes a few years ago, state licensing boards formulated some stringent and restrictive rules which many of the poor schools could not meet and they were forced to close. With the improvements that have occurred in medical education, many of the requirements might be rescinded. Schools that are recognized as giving good courses should arrange their own schedules, determine the type of internship which they think best and the number of hours which should be devoted to a subject. Their aim and desire is to graduate the highest type of student, who should be admitted to practice when graduating from such a school without examinations before state boards.

There are certain imponderables which determine one's ability to practice and these are not based on studies, schemes, curriculums or time schedules.

Address of Vice President, Rudolph Matas

The Speaker introduced the Vice President, Dr Rudolph Matas, who addressed the House.

Mr Speaker, Gentlemen of the House of Delegates

In this position of vice president we have an office that has been regarded as a sinecure. I thought that before this honor was conferred on me, but I have since reconsidered. During the past year of my incumbency as vice president I have been quite busy. The first part of the year, most of the year in fact, has been spent in praying and getting all the help that I could in all the churches for the preservation of the life of the President so that I might not be brought face to face with all the problems that he has had to deal with, and I am delighted to see that through divine intervention we have preserved our President and he maintains this magnificent presence that he gives us this morning.

That is one occupation, and you see that it is a serious one. The next has been the importance of my learning something of the problems that are involved in the American Medical Asso-

ciation in the event that the dire disaster should come and the President should fail and I should have to stand in his place. That has kept me very much worried and as a consequence the habit has been beneficial, for I have learned a great deal, things that I have never suspected, because I have been limiting myself to the surgical side, and now I have learned a great deal more about the executive work and particularly about the economics of the medical profession which I knew nothing about at all. So it has been educational and it has been useful to me through the honor and the utility that it has brought to me. It has been a very profitable year in making me acquainted with problems that I had never met before.

I appreciate this opportunity. What has been said to you before covers the ground, and I feel that what I have learned during the past year is quite sufficient to make me understand that I must not abuse your patience. You have too many problems to consider for me to be occupying your time now.

I only wish to thank your very distinguished and able Speaker and particularly the gentlemen present for this opportunity of meeting face to face the solons of the medical profession of America.

REPORTS OF OFFICERS

Report of the Secretary

Dr. Olin West then presented his report as Secretary, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary, with the exception of that portion relating to an amendment to the Constitution which was referred to the Reference Committee on Amendments to the Constitution and By-Laws.

Resolution on Death of Dr. Mitchell

The Secretary read the following resolution from the Board of Trustees commemorating the death of Dr. Albert R. Mitchell, which was made a matter of record:

The Board of Trustees of the American Medical Association at its session in Milwaukee, June 11, expresses its deep appreciation of the loyal constructive and understanding efforts of Dr. Albert R. Mitchell in behalf of the physicians of this country and its deep sense of personal loss in his death.

For seventeen years Dr. Mitchell attended practically without a single omission the meetings of the Board of Trustees and many of the sessions of its Executive Committee. He gave to the American Medical Association his best judgment and fought for its ideals and for the promulgation of plans for its development with an intensity that represented his whole spirit.

To the family of Dr. Albert R. Mitchell the Board expresses its sincere sympathy in the loss of this humane and socially minded physician.

Report of the Board of Trustees

The Secretary presented the report of the Board of Trustees, which was referred to the Reference Committee on Reports of the Board of Trustees and Secretary, with the following exceptions:

The report on the Bureau of Medical Economics was referred to the Reference Committee on Medical Economics, the report on the Bureau of Legal Medicine and Legislation to the Reference Committee on Legislation and Public Relations, the report on the Bureau of Health and Public Instruction, to the Reference Committee on Hygiene and Public Health, and the resolution at the end of the Board's report, to the Reference Committee on Rules and Order of Business.

Report of the Judicial Council

Dr. George E. Follansbee, Chairman, presented the report of the Judicial Council, which was referred to the Reference Committee on Reports of Officers.

Report of the Council on Medical Education and Hospitals

General Merritt W. Ireland, Washington, D. C., presented the report of the Council on Medical Education and Hospitals, which was referred to the Reference Committee on Medical Education.

Report of the Council on Scientific Assembly

Dr. Irvin Abell, Kentucky, presented the report of the Council on Scientific Assembly, which was referred to the Reference Committee on Sections and Section Work.

Report of the Committee on Legislative Activities

Dr. Charles B. Wright, Chairman, presented the following report, which was referred to the Reference Committee on Legislation and Public Relations:

Following the New Orleans meeting, Dr. West, Dr. Cary, Dr. Crockett and the chairman of the Committee on Legislative Activities were approached by influential members of the American Legion, who suggested that the members of the Association attend the meeting of the Rehabilitation Committee of the Legion, at Portland, Ore. Later Dr. West received an invitation from National Commander Stevens, asking for representation consisting of Dr. E. H. Cary, President of the American Medical Association, Dr. F. S. Crockett, a member of the auxiliary committee on veterans' affairs, and the chairman of the Committee on Legislative Activities. The group thus invited conferred in Chicago with Dr. West, and it was decided to accept the invitation. This decision was approved by the Board of Trustees.

We spent from Sept. 10 to 16, 1932, at the meeting named, where we were well received by the representatives of the American Legion. Dr. Cary was invited to speak before the convention of the Legion and did so. We conferred with the subcommittee of the Rehabilitation Committee of the Legion on Medical and Hospital Care, and on invitation we gave our views on the care of veterans, interpreting to the best of our ability the attitude of the profession. We conferred also with the medical director of the Veterans' Administration, Dr. Griffith, and the administrator, General Hines. For the first time we had an opportunity to discuss the situation with the administrator with the utmost frankness. He suggested that we meet him in Washington and go over some of the problems of the Veterans' Administration, particularly the problems relating to the cost of the care of veterans suffering from general medical and surgical disabilities.

A resolution was adopted by the Legion, asking that representatives of the American Medical Association be named to serve on the advisory committee of the National Rehabilitation Committee of the Legion, and at the request of the national commander of the Legion, approved by the Board of Trustees of the American Medical Association, Dr. F. S. Crockett and the chairman of the Committee on Legislative Activities were appointed on the advisory committee. So far there has been no meeting of the committee and no matters have been brought before us for consideration.

Following the Portland meeting we were formally invited by General Hines to a conference in Washington with the Veterans' Administration. On October 9, Dr. Cary, Dr. West, Dr. Crockett and the chairman of the Committee on Legislative Activities went to Washington and then spent two days there in conference with the administrator of veterans' affairs, and with Dr. Griffith and other representatives of the administration. At this conference General Hines outlined the program which later he recommended to Congress, calling for a very extensive reduction in the cost of the care of veterans.

Later the American Medical Association was invited to send its representatives before the Joint Congressional Committee on Veterans' Affairs. Dr. Cary and Dr. Woodward, director of the Bureau of Legal Medicine and Legislation, were delegated to appear. Their discussions are a matter of record and are accessible to any one in the published "Hearings Before the Joint Congressional Committee on Veterans' Affairs, Congress of the United States, 72d Congress, Second Session, Volume I." The Joint Committee later reported only that the control of veterans' affairs had been delegated to the President and that the situation was therefore, in the hands of the chief executive.

Very briefly stated, the formal activities of the committee have been related above. During all the time they were going on, however, Dr. Cary was discussing the problem of veterans' care before state medical associations and other medical organizations, and the committee was carrying on a voluminous correspondence. The chairman of the committee received and answered approximately one thousand letters from various parts of the country, from individuals and groups, asking for information concerning the situation. Judging from this correspondence and from reports in the press, county and state medical associations did a great deal of active work with reference to the problem of veterans' relief.

Prior to the change in the administration at Washington, President Hoover vetoed the Independent Offices Appropriation Act, containing the appropriation for the Veterans' Administration for the fiscal year 1933-1934. He thus left the slate clean for President Roosevelt. President Roosevelt, immediately following his inauguration, took the definite action with respect to this matter that is now familiar to all. It is unnecessary to call your attention to the efforts that are now being made to induce him to modify the action he took to effect economies in the cost of the Veterans' Administration. Free clinics have been established for veterans in various communities by the American Legion, and, on the basis of the observations and experiences of these clinics, demands are being made for the continuance of hospitalization and medical care for all classes of veterans. In addition to this, local communities and state legislatures have protested against the burden that has been thrown on them in the care of needy veterans.

As an illustration of the local interest in this problem, may I call your attention to House Joint Resolution 58, passed by the legislature of the state of Illinois, memorializing the Congress of the United States to include in the independent offices appropriation bill such provisions and appropriations as will permit the continuation of contracts between the federal government and the state to meet the emergency in the state of Illinois. The preambles to the resolution describe the situation as follows:

WHEREAS Since the ending of the World War due to an insufficient number of beds available for the care and treatment of mentally disabled veterans within federal hospitals Illinois state facilities have been utilized under contract with the Veterans Administration at a cost much less than the operating cost of the same comparable federal beds and as a result of which the state of Illinois has received from one hundred fifty to two hundred thousand dollars annually and

WHEREAS There are now being cared for in Illinois state institutions 1 050 mentally disabled veterans committed by various county courts and instructions issued by the Veterans Administration indicate existing contracts will become a responsibility of the taxpayers of the state of Illinois and further there are thousands of mentally disabled veterans in Illinois not confined in any institutions whose only means of livelihood for the most part will also be taken away and the balance greatly reduced which will obviously cause a great number of new commitments thereby forcing the state of Illinois to appropriate four hundred thousand dollars or more, for the biennium to meet the cost of care which these unfortunate veterans deserve or to refuse such care

The legislatures of other states have initiated similar action.

To illustrate the trend of congressional opinion, I call your attention to a bill, Senate 185, introduced by Senator George. This bill proposes to provide, through an amendment to an act already in force, for the "Donutary care to all persons honorably discharged from the Army, Navy, or Marine Corps of the United States where they are suffering with permanent disabilities, tuberculosis or neuropsychiatric ailments and medical and hospital treatment for diseases or injuries. Just how far reaching the proposed act would be, cannot at this time be determined.

Just how many veterans need care who cannot obtain it is not known. We have no facts on which to determine the number, although we have fairly definite opinions. This is a matter which should receive careful consideration by our state and county medical organizations. We urge that they interest themselves and cooperate in the readjustments in caring for needy veterans, made necessary by recent congressional and presidential action. We should obtain as definite information as is ascertainable concerning the extent of the problem, so that we may be in a position to advise properly as opportunities arise.

To conclude the discussion on veterans' affairs, it is our opinion that the American Medical Association should support the President of the United States in his exercise of the authority that has been conferred on him. The Congress has granted him authority to determine the nation's policy in regard to veterans. He has acted courageously, according to his best judgment. If events prove that he has made an error of judgment, he will, we believe, promptly correct that error on his own initiative. Your committee deplors the attempts that have been and are being made to deprive the President of the authority that has been granted to him.

We believe that it is the duty of the government to provide medical and hospital service at government expense for the relief and cure of such disabilities of veterans as are of service origin. This service could be rendered in government hospitals

and homes, or elsewhere, in whatever manner is of the greatest benefit to the disabled veterans. The President has promised such care to veterans of this class. We believe further that care of this type should be provided at government expense for veterans disabled by neuropsychiatric and tuberculous disorders and for veterans totally disabled by other chronic diseases, and by injuries, when those veterans are unable to provide for themselves. Finally, however, we are of the opinion that medical and hospital service for the treatment of acute medical and surgical diseases of veterans should be provided in all cases by the communities in which the veterans reside, such diseases being obviously not of service origin. Veterans in such cases should be treated in exactly the same manner as are other members of the community in which the veteran resides. We believe that this course is in the best interests of the veterans themselves.

We must recognize that injustice and inequalities incorporated into the law, on the demands of special groups and individuals—in many instances not at the request of the American Legion—over a period of years, by congresses too liberal with the taxpayers' money cannot be corrected overnight. We believe that the President will do his best and that he should be supported. We recommend that he be advised of the attitude of the American Medical Association with respect to this matter.

Changing the subject we call attention to the excellent work that is being done by the Bureau of Legal Medicine and Legislation. Exact information is always available through this bureau on legal aspects of the practice of medicine and on legislative activities, both state and national. A brief résumé of the activities of this bureau was published in the April number of the AMERICAN MEDICAL ASSOCIATION BULLETIN.

Finally, may we call attention to another matter that is, we believe, of vital interest to the public and the medical profession that is, the corporate practice of medicine. The courts in a number of states have held that the corporate practice of medicine is unlawful. If this can be legally established throughout the country, it will do a great deal now and in the future to protect the public and the medical profession from exploitation. We urge delegates to stimulate interest in this matter in their respective state organizations. Exact information concerning it is available in the Bureau of Legal Medicine and Legislation.

Respectfully submitted

COMMITTEE ON LEGISLATIVE ACTIVITIES
CHARLES B. WRIGHT, Chairman

(To be continued)

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday from 9:15 to 9:20 a.m., Chicago daylight saving time, which is one hour faster than central standard time, over Station WBBM (770 kilocycles, or 389.4 meters).

The subjects for the week are as follows:

June 27 Holiday Traffic Tragedies.
June 29 Vacation on Tour

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9:45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

July 1 Look Out for Sunburn

Education of the Public—Education for a higher allotment of the budget to medical care carried out directly by the physician is largely ineffective for under the circumstances he is assumed to be a special pleader. This reaction is always aroused whenever the profession attempts through legislation to raise the standards of licensure or to enforce public health measures and frequently blocks such attempts. Education of the public is preferably, then, a responsibility of the public health services and should be recognized as such—Harvey, S. C. *Oikonomia Medika, Jale J Biol & Med* 5:323 (March) 1933.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Personal—Dr Benjamin D Luck, Pine Bluff, was recently made a member of the state board of nurse examiners, succeeding Dr Mahlon D Ogden Little Rock.—Dr Allen B Jemison has been elected director of the Jefferson County Health Department, succeeding Dr George A Hays, resigned.

Society News—At the meeting of the First Councilor District Medical Society in Piggott, May 24 speakers included Drs Joel C Land, Walnut Ridge, on asthma, William T Black Memphis, Tenn, uterine bleeding, Robert Lyle Motley, Memphis, heart disease, and Junius B Futrell Rector, obstetric complications.

CONNECTICUT

Professor Ferris Resigns—Dr Harry Burr Ferris has resigned as professor of anatomy and head of the department at Yale University School of Medicine a position he has occupied since 1895. Dr Ferris who is 68 years of age, received his medical degree from Yale University School of Medicine in 1890. He became an instructor in anatomy at the medical school in 1892 assistant professor and in 1895 professor, and was appointed E. K. Hunt professor of anatomy in 1897. Dr Ferris will be succeeded at Yale by Edgar Allen, Ph D, dean of the University of Missouri School of Medicine, Columbia, July 1.

FLORIDA

Reorganization of Health Department—Reorganization of the Tampa Health Department, which was recently recommended to the city board of aldermen was to have been effected June 1 with the adoption of a new city budget. Service of part time physicians on the staff will be discontinued, and two physicians will be employed on a full time basis. A net saving of \$5,120 a year under the new plan is anticipated.

Whitehurst Sentenced—Tyree C Whitehurst was recently sentenced to five years in the federal prison at Atlanta following his conviction of having used the mails in connection with a scheme to represent himself as a doctor it is reported. In pronouncing sentence, Judge Ackerman is said to have stated:

In this case I am convinced that you are a professional abortionist and under the circumstances I feel it my duty to the community to put you where you cannot continue this nefarious practice.

Whitehurst has also been convicted of practicing medicine without a license (THE JOURNAL, Jan 24, 1931, p 277). At that time he was given a sentence of a year and a day in the state prison at Raiford. Whitehurst claimed at one time that he graduated from the University College of Medicine, Richmond, Va, in 1898 and that he was licensed in Florida in 1915. Examination of the alumni list showed that he was not a graduate of the university college or of the Medical College of Virginia which absorbed the former institution in 1913. There is said to be no record that a Florida license was ever issued to him.

ILLINOIS

Physicians Honored—The Christian County Medical Society gave a dinner, May 31, in honor of Drs George J Rivard, Assumption, Campbell A Stokes, Edinburg and Joseph F Miller, Palmer, veteran members of the society in point of service. Dr Rivard has spent fifty-two years in the practice of medicine in the county, Dr Stokes fifty-one years, and Dr Miller forty-five years.

Society News—Dr Horace W Soper, St Louis, addressed the St Clair County Medical Society June 1, on "Diagnosis of Diseases of the Rectum and Colon."—Dr Oscar T Schultz, Evanston, among others addressed a joint meeting of the Vermilion County Medical Society and the Vermilion Bar Association, Danville, May 2, on "Relation of Medicine to Law in the Administration of Justice."—Dr James Curtis Lyter, St Louis, addressed a recent meeting of the Union County Medical Society at Anna on diseases of the coronary arteries.—Dr Frank H Lahey, Boston, addressed the Winnebago County Medical Society, Rockford, June 13, on "Malignancy of the Colon and Rectum."

Milk-Borne Epidemic—Thirteen cases were involved in the only epidemic in Illinois in 1932 that was directly attributable to contaminated milk, according to *Illinois Health Messenger*. The disease, an infection for the most part fairly characteristic of scarlet fever was limited strictly to users of one unpasteurized milk supply. In one family of three members, two who drank only pasteurized milk escaped the disease, while the other member who used raw milk from the dairy in question became ill. Of the thirteen patients, ten had a rash fairly typical of scarlet fever. Most of them had some degree of sore throat. It was officially reported that an employee at the dairy had scarlet fever. The cow yielding milk with positive evidence of hemolytic streptococci was removed from the herd and the sale of milk from the dairy was discontinued temporarily.

CHICAGO

Faculty Changes at Loyola—Recent appointments to Loyola University School of Medicine include the following:

Gregory R Waters, clinical assistant in dermatology.
Herbert E Landes, clinical professor in genito-urinary surgery.
Chester H Warfield, assistant professor in the department of medicine.
Irvin F Hummon, assistant in anatomy.
Salvatore J Nigro, clinical assistant in gynecology.
Irving Francis Barnett, clinical instructor in ophthalmology.
Jerry J Kearns, clinical assistant in surgery.

Society News—Dr Roberto Alessandri, director of surgery, Royal University of Rome, lectured on "Surgery of the Stomach" at Columbus Hospital, June 10, a dinner in his honor preceded the talk.—Dr E Gorter, Leiden, Holland addressed the Chicago Pediatric Society, May 20, on "Copper and Anemia in Childhood."—Dr Anton J Carlson spoke, among others before the Chicago Society of Internal Medicine May 22, on "Endocrinology in the Laboratory and in the Clinic."—Drs Aaron E Kanter and Perry J Melnick presented a paper on "Thecomas of the Ovary" before the Chicago Gynecological Society June 16, and Drs William M Spear, Oakdale, Iowa, and Henry C Hesselstine, one on "Significance of Menstrual Disturbances in Pulmonary Tuberculosis."

Two Millions for a Dental Clinic—More than \$2,000,000 has been bequeathed to the University of Chicago by the late W G Zoller to establish and maintain a free dental dispensary, according to the *Chicago Tribune*. The income will be used by the university for the purpose of equipping and maintaining dispensaries and laboratories and to supply competent and skilful dental service, including diagnostic aids to the needy and poor, free of charge in such manner that the greatest number of people may secure skilful treatment to enable them to be relieved and to prevent the numerous ills which result from neglect of the teeth." Other benefactions include \$10,000 each to the Central Free Dispensary and the Home for Destitute and Crippled Children, and \$5,000 to the Chicago Home for Incurables. Mr Zoller was formerly vice president and treasurer of the Bell and Zoller Coal Company.

INDIANA

Society News—Dr Lewis J Pollock, Chicago spoke before the St Joseph County Medical Society in South Bend, May 31, on "Common Conditions Met in Clinical Neurology."—At a meeting of the Porter County Medical Society in Valparaiso, May 31, Dr Arthur G Miller Hobart, lectured on "Female Sex Hormones."—The Jasper-Newton Counties Medical Society heard Dr Harry E Mock, Chicago, discuss "Traumatic Head Injuries," at its meeting in Kentland, May 26.—Dr John Sater Nixon, Indianapolis, addressed the Morgan County Medical Society, May 17, on "Early Diagnosis of Acute Appendicitis."

IOWA

Society News—Drs Francis L Lederer and Frederick H Falls, Chicago, addressed the Dubuque County Medical Society at Dubuque May 9 on "Modern Concepts in the Diagnosis and Treatment of Sinus Conditions and 'Pregnancy and Tuberculosis,' respectively.—The Black Hawk County Medical Society, Waterloo, was addressed, May 16, by Dr Cyrus W Rutherford, Iowa City, on squint, and Dr Carl L Nelson Waterloo, on appendicitis in childhood.

MARYLAND

Lectures on History of Medicine—Dr Henry E Sigerist, director Institute of the History of Medicine, Johns Hopkins University School of Medicine, Baltimore, opened a series of lectures at the University of Maryland, March 16 on the history of medicine. Dr Owsei Temkin and Dr John Rathbone Oliver associates in the history of medicine, Johns Hopkins, spoke March 23 and 30, respectively. Dr Oliver also delivered lectures in this series on consecutive Thursdays through May 4.

Society News—Dr Arthur G Barrett, Baltimore was installed as president of the Maryland Academy of Medicine and Surgery for his sixteenth consecutive term at its annual meeting, April 18. Dr Thomas B Fletcher, among others, spoke on "The Pituitary Gland and Its Diseases"—Dr William Fletcher Shaw, professor of gynecology and obstetrics, University of Manchester, England, addressed the gynecologic and obstetric section of the Baltimore City Medical Society, May 11, on maternal mortality.

Advisory Committee on Sanitation—The appointment of an advisory committee on sanitation to serve the Baltimore Health Department especially on matters of environmental hygiene, has been announced. Dr William H Howell, director emeritus of the Johns Hopkins School of Hygiene and Public Health, is chairman of the committee. Wilmer H. Schulze, who since 1929 has been chief of the division of chemical technology, was made director of the new bureau of environmental hygiene in the health department.

Personal—Dr William H Wilmer, director of the Wilmer Institute of Ophthalmology, Johns Hopkins University School of Medicine, Baltimore, received, March 25, the decoration of the Angelo Secchi Academy of Science from Georgetown University, Washington, D C, where, for nineteen years, he was a member of the faculty. Presentation was made on the university's celebration of Founders Day.—Dr Adolf Meyer, director of the Phipps Psychiatric Clinic of Johns Hopkins Hospital, Baltimore, delivered the fourteenth Maudsley lecture of the Royal Medico-Psychological Association in London, May 17. His subject was "Psychiatry and Mental Hygiene."

MASSACHUSETTS

Campaign to Reduce Appendicitis Deaths—June 12 opened a week's campaign of education in Massachusetts to reduce deaths from appendicitis. In Philadelphia, mortality from acute appendicitis was materially reduced following a campaign of education. Cooperating in the Massachusetts campaign were the state department of health, the state pharmaceutical association, the Boston Retail Druggists' Association, and the public health committee of the Massachusetts Medical Society.

Portraits Presented—At a dinner, May 5 portraits of Dr Harvey Cushing and Dr Henry A. Christian were presented to Harvard University Medical School and Peter Bent Brigham Hospital, Boston, respectively. Dr Cushing recently retired as Moseley professor of surgery at the university, and Dr Christian, professor of the theory and practice of physic at the university is physician in-chief to the hospital. He was dean of the medical school from 1908 to 1912. The dinner was attended by the faculty of the university and the governing boards of both university and hospital.

MINNESOTA

Personal—Dr Albert E. Olson, Duluth, has been appointed a member of the board of regents of the University of Minnesota.—Dr Edward A. Meyerding, St Paul, has been promoted to the grade of colonel in the medical reserve corps.

Basic Science Law Violations—Mitchell Jurdy, "naturopathic physician and physical culturist, was sentenced, recently, to serve six months in the Minneapolis Workhouse, for practicing healing without a basic science certificate. As this was the second offense of Jurdy, the sentence was not suspended. In 1932 Jurdy pleaded guilty to a similar charge, having treated a patient with epilepsy, it was claimed. In the recent instance, Jurdy was said to have treated a patient suffering with Hodgkin's disease. C. W. Brunelle, alias "Chief Little Cloud" pleaded guilty at Faribault to a charge of practicing healing without a basic science certificate, March 30. "Chief Little Cloud" is a half breed Chippewa Indian and is employed by the city of Minneapolis as a garbage collector. During his spare moments, and particularly on Saturday afternoons and Sundays he has been making a specialty of driving down to Faribault to see a number of patients," the state board reports. In the present instance he was alleged to have diagnosed the ailment of a woman as "bone rheumatism" and left some medicine, making a charge of \$7.

MISSOURI

Dr Conley Appointed Dean—Dr Dudley S. Conley, Columbia, professor of surgery, University of Missouri School of Medicine, has been appointed dean of the institution to succeed Edgar Allen Ph.D., at the beginning of the next school year. Dr Conley, who graduated from Columbia University College of Physicians and Surgeons, New York, in 1906, has been connected with the University of Missouri since 1919.

Dr Allen will become professor and head of the department of anatomy at Yale University School of Medicine, New Haven. He has been dean of Missouri since 1930 and professor of anatomy since 1923. From 1919 to 1921 he was instructor and associate in anatomy, Washington University School of Medicine.

New Health Officer and Hospital Commissioner of St. Louis—Dr Joseph F. Bredeck assumed the duties of health commissioner of St. Louis, April 20 replacing Dr Max C. Starkloff, who served in the position for thirty-two years. Dr Bredeck graduated from Washington University School of Medicine in 1914. He was licensed in the same year. In 1917 he received the degree of doctor of public health from the University of Pennsylvania. Dr Ralph L. Thompson, since 1907 professor of pathology, St. Louis University School of Medicine, was recently appointed hospital commissioner of St. Louis, succeeding Dr Curtis H. Lohr. Dr Thompson is also director of the National Pathological Laboratory in St. Louis. He graduated from Harvard University Medical School in 1900. For three years previous to his appointment in 1929 as hospital commissioner, Dr Lohr was superintendent of the isolation hospital (THE JOURNAL, June 15, 1929, p. 2029).

NEW JERSEY

Personal—Dr Jacob Allen Patton, Newark, medical director and second vice president of the Prudential Life Insurance Company, will retire from active duty with the organization, July 1 after thirty-eight years of service, and will make his home in California. Dr Patton, a graduate of Rush Medical College, Chicago, became associated with the Prudential company in 1895.

NEW MEXICO

State Medical Election—Dr Henry A. Ingalls, Roswell, was inducted into office as president of the New Mexico Medical Society at its annual meeting May 19, and Dr Charles F. Milligan, Clayton was named president-elect. Dr Leo B. Cohenour, Albuquerque, was reelected secretary. The next annual session will be held in Las Vegas in May, 1934.

NEW YORK

Personal—Dr James L. McCartney, director of classification, New York State Department of Correction, has been awarded a grant of \$1,000 by the Thomas W. Salmon Memorial Committee of the New York Academy of Medicine to investigate the classification of prisoners and draw up a handbook on classification for use in prisons.

Dr Chapin Given University Medal—At the commencement exercises of Columbia University June 6 Nicholas Murray Butler, president, presented the University Medal for excellence to Dr Henry Dwight Chapin, emeritus professor of diseases of children, New York Post-Graduate Medical School and Hospital, New York. The medal was awarded to Dr Chapin in recognition "of his outstanding contribution to problems relating to the care of children."

Letchworth Village Nears Completion—Appropriate ceremonies marked the laying of the cornerstones for eleven new buildings at Letchworth Village, June 14. The completion of these structures, which will be within a year, will make this the largest state institution for mental defectives, according to the *State Charities Aid Association News* and will complete the original building program proposed in 1908. With a total of ninety-three buildings in use, covering 2,234 acres of ground, there will be accommodations for 3,500 mentally defective children. Dr Charles S. Little, the first superintendent, is still in charge of the institution.

Anniversary of Antituberculosis Campaign—The twenty-fifth anniversary of the antituberculosis campaign in upstate New York was observed June 8, at the annual Conference of State and Local Committees on Tuberculosis and Public Health of the State Charities Aid Association. Among the speakers were Gov. Herbert H. Lehman, who spoke on "The State's Interest in the Control of Tuberculosis," and Dr Thomas Parran, Jr., state health commissioner, on "Common Interests Between the Control of Tuberculosis and Syphilis." In 1908, tuberculosis was said to be the greatest single cause of death in the commonwealth, with a rate of 151.9 per hundred thousand of population. A rate of 59.2 was recorded in 1932, a reduction of 61 per cent.

New York City

Annual Etching Exhibition—The Haden Etching Club, composed of dentists and physicians whose hobby is etching, held its second annual exhibition at the Kennedy Galleries, May 15-27. The club is named in honor of Sir Francis Sey-

mour Haden, a surgeon and an etcher Edward Kennedy, DDS, was the prize winner for his etching and aquatint, 'Gulls' Other exhibitors included

Dr Hermann Fischer	Dr Joseph F Saphir
Dr Leigh Harrison Hunt	David Schoen DDS
Dr Haver P Mosher Boston	Walter C. Sinnigen DDS
Dr Elmer M. Melicon	Bernhard W. Weinberger DDS
Dr Henry Minsky	Dr Henry Smith Williams
Dr Benjamin F Morrow	Harold S. Vaughan, M D DDS

Only two of the exhibitors, Charles Berger, DDS, and Dr Laurence D Redway, depicted medical subjects in their compositions

Department of Forensic Medicine—The establishment of a department of forensic medicine at the University and Bellevue Hospital Medical College has been announced. Medical examiners and toxicologists will be trained in the department, which is considered an initial step toward establishing a system of scientific crime detection in this country to correspond with the system of medicolegal institutes of continental Europe. Dr Charles Norris, chief medical examiner of New York, will head the department as professor of forensic medicine and Dr Harrison S. Martland, chief medical examiner of Essex County, Newark, N. J., has been named associate professor. Other members of the department will include Alexander O. Gettler, Ph.D., city toxicologist, who will become professor of toxicology, Dr Douglas Symmers, director of laboratories at Bellevue Hospital, who will be professor of gross pathology, Dr Armin V. St. George, assistant professor of gross pathology, and Dr Thomas A. Gonzales, deputy chief medical examiner of New York, assistant professor of forensic medicine. The curriculum planned by the new department will include a required short course to fourth year medical students, covering salient points as to what constitutes medical examiners' cases, proper signing of death certificates, and testimony in court, an optional laboratory course to fourth year students consisting of a month's work in the medical examiner's office assisting at necropsies, a graduate course of three years in the office of the medical examiner leading to a degree, and a graduate course of two years in toxicology leading to a degree. The required course for seniors will consist of six lectures. Laboratory work for fourth year students and graduates will include attendance at necropsies, the taking of postmortem notes and laboratory work in connection with microscopic examination of sections and bacteriological examinations.

NORTH DAKOTA

State Medical Election—Dr Jesse W. Bowen, Dickinson, was inducted into office as president of the North Dakota State Medical Association at its annual meeting, June 1-2, in Valley City. Dr Clyde E. Stackhouse, Bismarck, was named president-elect. Other officers elected are Drs Archibald D. McCannell, Minot, and William A. Gerrish, Jamestown, vice presidents, Dr William W. Wood, Jamestown, treasurer, and Dr Albert W. Skelsey, Fargo, reelected secretary.

OHIO

Personal—George B. Ray, Ph.D., associate professor of physiology, Western Reserve University School of Medicine, Cleveland, has been appointed professor of physiology and pharmacology at Long Island College of Medicine, succeeding Dr John C. Cardwell, retired.—Dr Benjamin H. Biddle, Sugar Grove, has been elected health commissioner of Fairfield County, succeeding Dr William R. Coleman, Bremen.—Dr Raymond T. Holzbach has been appointed health commissioner of Salem, succeeding Dr Thomas T. Church.

Fifty Years in Practice—The Miami County Medical Society honored Dr Gaius Jennings, West Milton, with a dinner May 5, in recognition of his fifty years of medical practice. In addition to presenting him with a floral tribute the society adopted a resolution eulogizing Dr Jennings. Dr Jerold K. Hoener, Dayton, was the guest speaker on "Occiput Posterior Position." Other physicians recently honored for completion of many years in the practice of medicine are Drs Albert A. Brooks, Orrville, fifty-one years; Henry E. Beebe, Sidney, sixty years; William H. Hawley, College Corner, forty-eight years; J. Eugene Baker, Marion, fifty years, and Robert G. Steele, Melmore, fifty years.

Part Payment Plan—A diagnostic and consulting service on a part pay basis for persons unable to meet full charges was placed in operation by the Academy of Medicine of Cleveland, June 5, following a study by the committee on economics. A card, indicating the percentage of payment he can afford, will be given the patient following an investigation of his financial condition for which a fee of fifty cents is charged. He will then be referred back to his physician or to a specialist selected by him from a list of the academy's members. The

academy will not refer any patients to specialists. Should a patient apply on his own volition for a rating, he will be referred to his family physician. If he has none, he will be asked to make his own selection from a list of general practitioners in his own locality furnished by the academy. The specialist will determine from the information on the card the percentage of his regular fee to be charged. The academy will furnish the specialists with form postcards to be filled out and returned.

Society News—Dr William E. Thompson, Bethel, 98 years of age, was the guest of honor at a meeting of the Clermont County Medical Society, May 17, he reviewed the changes in medicine and medical practice during his seventy years in the profession.—The Logan County Medical Society held a round table on blood deficiency diseases, May 5, at Bellefontaine.—Speakers before the May meeting of the Ashtabula County Medical Society were Drs Jacob E. Tuckerman on "Chronic Malaria," and Clarence H. Heyman, both of Cleveland "Disabilities at the Knee Joint."—A recent meeting of the Lorain County Medical Society at Lorain was addressed by Dr Hubert C. King, Lakewood, on "Heart in Toxic Goiter."—The Mahoning County Medical Society and the Mahoning County Bar Association will be addressed, June 27, by Attorney F. R. Hahn, Youngstown, and Dr Edwin A. Hamilton, Columbus on medicolegal considerations from the standpoint of the lawyer and physician, respectively.—Dr Harry Lee Huber, Chicago, addressed the Toledo Academy of Medicine, June 2, on "Development of Pollen Therapy."

Steuer Prize Awarded—Western Reserve University School of Medicine recently awarded the Steuer Prize in anatomy to William B. Seymour, Jackson, Mich., a sophomore for his volunteer study, last summer, of bone scars revealed by the X-rays in the limb bones of children, caused by piling up of lime when illness, dietary disturbances or shock temporarily stops growth. By examining 3,700 records, Seymour was able to chart the growth of the limb bones from infancy till completion of growth at about 18. His study also establishes that growth of the limbs reaches maximum at the age of 14. The Steuer Prize is a memorial to the late Dr Herbert S. Steuer, a graduate of the college in 1921, whose death occurred in the Cleveland Clinic disaster in 1928. Frederick Robert Mautz, Marion, senior, was awarded two prizes at the commencement, June 14, when he received his degree of doctor of medicine. One, the gift of Dr Edwin C. Garvin, class of 1894, is the income from a fund, given annually, to a member of the fourth year class who shows best knowledge, theoretical and practical of obstetrics. The second is the senior prize in surgery, conferred annually on the student in the graduating class who has shown best knowledge and greatest ability in surgery during his undergraduate course. This is the gift of Dr Elliott C. Cutler, formerly professor of surgery at the school and now occupying a similar position at Harvard University Medical School, Boston.

OREGON

Personal—Dr Wilford H. Belknap, Portland, was elected president of the alumni association of the University of Oregon Medical School at the annual session, March 8. Dr Birchard A. Van Loan, Portland, succeeded Dr Belknap as secretary.—Dr and Mrs David M. Brower, Ashland, celebrated their fiftieth wedding anniversary, recently.

PENNSYLVANIA

Society News—Dr Armitage Whitman, New York, gave an address before the Huntingdon County Medical Society at Huntingdon, June 8, on infantile paralysis.—At a meeting of the Lycoming County Medical Society in Williamsport, June 9, Drs Louis H. Clerf and Charles Mazer, Philadelphia, spoke on "Relation of Bronchoscopy to General Medical Practice" and "Phases of Endocrine Therapy," respectively.—A symposium on genito-urinary disease was presented before the Dauphin County Medical Society, June 6, by Drs John Oeslager, Jr., John L. Lanshe and Samuel Grossman.—At a meeting of the Harrisburg Academy of Medicine, May 16, Dr Charles M. Wainwright, Jr., Baltimore, spoke on "Bromide Poisoning."—Dr George W. Crile, Cleveland, will be the guest speaker before the annual meeting of the Lehigh Valley Medical Society, July 31, in Mount Pocono.

Philadelphia

Dr Riesman Resigns as Professor—Dr David Riesman resigned recently as professor of clinical medicine at the University of Pennsylvania School of Medicine, a position he has occupied since 1912. He will continue as professor of

the history of medicine at the institution. Dr Riesman's last lecture as professor of clinical medicine dealt with a physician's conduct in relation to his fellow practitioners and his duties as a citizen.

Dr Meeker Honored—George H Meeker, LL.D., dean of the Graduate School of Medicine, University of Pennsylvania, since he established it in 1918, was honored at a dinner, June 1. A portrait of Dr Meeker was presented to the university by Dr George Morris Piersol on behalf of those in attendance and accepted by Dr Alfred Stengel, vice president in charge of medical affairs. Josiah H Penniman LL.D., provost of the university, was among the speakers and Dr George E de Schweinitz, emeritus professor of ophthalmology, presided. Dr Meeker also founded the department of pharmaceutical chemistry at the university in 1907 and continued as its dean to 1916, since which time he has been professor of chemistry at the University of Pennsylvania School of Medicine.

Professors Appointed—Drs George M Coates John Clayton Gittings and Isaac Starr, Jr., were recently appointed to professorships at the University of Pennsylvania School of Medicine. Dr Coates succeeds the late Dr George Fetterolf as professor of otolaryngology. He is at present professor of otorhinology in the university graduate school of medicine and in addition is chief of the department of otolaryngology at Presbyterian and Abingdon Memorial hospitals, associate surgeon to the ear, nose and throat department of Pennsylvania Hospital, and consulting surgeon to several other institutions. He is secretary of the American Laryngological Association. Dr Gittings, formerly professor of pediatrics, returns as the first regular incumbent of the William H Bennett professorship of pediatrics. He has been president of the Philadelphia Pediatric Society and the American Pediatric Society and is now professor of pediatrics in the graduate school of medicine. Dr Starr was appointed instructor in 1922, has since served as associate in medicine and assistant professor of clinical pharmacology, and now becomes the first Milton B Hartzell professor of research therapeutics. The chair was endowed by the late Dr Hartzell, who was professor of dermatology in the school of medicine. The new professors are graduates of the University of Pennsylvania.

Hospital Purchases Franklin Manuscript—The original manuscript of an inscription written by Benjamin Franklin for the cornerstone of the Pennsylvania Hospital, which was recently discovered in Germany and acquired by A. S. W. Rosenbach, Philadelphia bibliographer and dealer in rare books, has been bought by the hospital. Funds for the purchase were provided by contributors to the hospital through Dr Francis R. Packard who presented the manuscript at the annual meeting of contributors, May 1. The inscription reads:

In the Year of Christ
1755
George the Second happily reigning
(For he sought the happiness of his People)
Philadelphia flourishing
(For its Inhabitants were publick spirited)
This Building
By the Bounty of the Government
And of many private Persons
Was piously founded
For the Relief of the Sick and
Miserable.
May the God of Mercies
Bless the Undertaking!

It is not known how the document happened to be in Germany. It was at one time in the possession of Robert Vaux, who was a manager of the hospital from 1823 to 1834. Franklin was the founder of the Pennsylvania Hospital, one of its designers and the author of two books about it.

TENNESSEE

Personal—Dr Howard M. Francisco, Bolivar, has been appointed superintendent of Eastern State Hospital, Lyons View, succeeding Dr R. E. Lee Smith.—Dr Harley W. Qualls, Memphis, was recently elected secretary of the Tennessee State Board of Medical Examiners to succeed the late Dr Alfred B. DeLoach.

Reorganization of State Health Department—Activities of the Tennessee State Department of Health have been necessarily curtailed because of the reduction of almost 50 per cent in the appropriation for public health work. In the reorganization of the department, the services suffering the greatest reduction include those on tuberculosis and malaria control and trachoma work. Dental hygiene has been completely eliminated and health education and public health nursing have been reduced to a minimum.

TEXAS

Hospital News—A new U. S. Marine Hospital at Galveston was dedicated in March, the hospital plant includes eight buildings.

Health at El Paso—Telegraphic reports to the U. S. Department of Commerce from eighty-five cities, with a total population of 37 million, for the week ended June 10 indicate that the highest mortality rate (191) appears for El Paso, and that the rate for the group of cities as a whole, 111. The mortality rate for El Paso for the corresponding period last year was 137 and for the group of cities, 107. The annual rate for eighty-five cities for the twenty-three weeks of 1933 was 117, as against a rate of 12.2 for the corresponding period of the previous year. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

VIRGINIA

Portraits Unveiled—Portraits of Dr Lewis Webb Chamberlayne, first professor of materia medica and therapeutics, and Dr Richard L. Bohannon, first professor of obstetrics and diseases of women and children, were unveiled during commencement week at the Medical College of Virginia, Richmond, recently.

WEST VIRGINIA

State Medical Election—Dr Roy B. Miller, Parkersburg, was named president of the West Virginia State Medical Association at its annual meeting, May 22, to serve from Jan. 1, 1934. Dr Delivan A. McGregor, Wheeling, now fills the presidency. Mr Joe W. Savage, Charleston, was reelected executive secretary. The next annual session will be held at Huntington in May or June, 1934.

Dr McClue Appointed State Health Commissioner—Dr Arthur E. McClue, New Cumberland, has been appointed health commissioner of West Virginia to succeed Dr William T. Henshaw, whose unexpired term would end May 31, 1935. Dr McClue is 35 years of age and a 1925 graduate of the University of Louisville School of Medicine, Louisville. He was formerly health officer of Hancock County. Dr Henshaw had been state health commissioner since 1921.

Heart Association Organized—The West Virginia Heart Association was formed at a meeting of the heart committee of the West Virginia Medical Association, May 22. Dr Oscar B. Biern, Huntington, was made president, Dr George H. Barksdale, Charleston, vice president, and Dr Raphael J. Condry, Elkins, secretary. Objectives of the newly formed society will be to gather and to disseminate information on the prevention and care of heart disease and develop and apply a uniform classification and study of heart disorders. When certain requirements have been accomplished the society hopes to become affiliated with the American Heart Association.

Society News—Dr James E. Hubbard addressed the Cabell County Medical Society in Huntington, May 11, on "Cancer of the Buccal Mucous Membrane" and Dr Chauncey B. Wright, "Fracture of the Jaw."—The Kanawha Medical Society recently heard Drs. Hugh A. Bailey and Robert King Buford, Charleston, discuss "Newer Methods in the Postoperative Management of Peritonitis Following Appendicitis" and "Borderline Hyperthyroids," respectively.—At a meeting of the Mercer County Medical Society in Princeton, recently, Dr John E. Cannaday, Charleston, spoke on "Surgical Aspect of the Gallbladder," and Dr Pat A. Tuckwiller, Charleston, "Jaundice."—Dr Moritz F. Petersen, Charleston, among others, spoke on "Diarrhea in Infancy" before the Fayette County Medical Society, May 9.—The Logan County Medical Society was addressed, May 17, by Drs. George F. Grisinger and Tyler R. Bohling, both of Beckley, on "Collapse Therapy in Tuberculosis" and "Tuberculous Laryngitis," respectively.—Dr Louis J. Karnosh, Cleveland, addressed the Ohio County Medical Society, Wheeling, June 2, on "A Psychiatrist's Anthology."

WISCONSIN

Personal—Dr Elmer Klein, Baltimore, has been appointed director of the Milwaukee County mental hygiene clinic, succeeding Dr Roy E. Bushong, resigned.—Dr Harry E. Purcell was recently named president of the board of health of Madison.

Society News—Dr Arthur W. Rogers, Oconomowoc, was guest speaker before the Brown-Kewaunee County Medical Society, April 19, on mental disease.—Judge William E. Hailey discussed legislative problems concerning social medi-

cine before the April meeting of the Douglas County Medical Society.—At a meeting of the Eau Claire and Associated Counties Medical Society April 24 the speakers were Drs. Oswald S. Wyatt, Minneapolis, on "Appendicitis in Childhood," James B. Carey, Minneapolis, "Diverticulitis of the Colon," and Harold E. Richardson, St. Paul, "Cardiac Neurosis."—Dr. William A. Wagner, Oshkosh, addressed the April meeting of the Manitowoc County Medical Society on "Complications of Pregnancy—Their Treatment and Prevention."—The Pierce St. Croix County Medical Society heard Judge O. Warnquist, judge of St. Croix County, speak May 11 on law relating to the indigent sick, and Dr. Hartwick M. Stang, Eau Claire, "Genito-Urinary Problems of Interest to the General Practitioner."—Dr. John A. Urner, Minneapolis, addressed the Polk County Medical Society April 20 on "Contraception and the Recent Developments."—The physicians of Vernon, Monroe and Juneau counties organized a tricity medical society May 11 and elected Dr. Arthur E. Winter, Tomah, president. Dr. Gunnar Gundersen, La Crosse, spoke on "Pyloric Obstruction."—Speakers before the Central Wisconsin Society of Ophthalmology and Oto-Laryngology at Wisconsin Rapids May 15 included Dr. Erling W. Hansen, Minneapolis, on "Syphilis of the Ear, Nose and Throat."

GENERAL

Journal Transferred—Beginning in January 1934 the *Journal of Nutrition* will be published by the Wistar Institute, Philadelphia, instead of the American Institute of Nutrition. Acquisition of the journal is said to be the first step in the creation of a department of nutrition at the Wistar Institute.

Hebrew Medical Journal—The third issue of the *Hebrew Physician* said to be the only medical journal published in Hebrew outside of Palestine has recently appeared. It contains seven major original articles and sections on Palestine and Medicine, Talmud and Medicine and Hebrew Medical Terminology, in addition to book reviews and summaries in English of the articles. Dr. Moses Einhorn, New York, is editor. The journal is published occasionally.

Dr. Willstaetter Awarded Medal—Dr. Richard Willstaetter, Munich, has been awarded the Willard Gibbs Medal of the Chicago Section of the American Chemical Society. The medal will be presented to Dr. Willstaetter September 13 during the eighty-sixth annual meeting of the American Chemical Society in Chicago. The award is made particularly for Dr. Willstaetter's work in the chemistry of chlorophyll. His research with cocaine alkaloids culminated in the synthesis of cocaine and made possible the commercial synthesis of local anesthetics. He attached the quinnines and quinnoid substances and discovered orthoquinone and proof of the structure of aniline black. Dr. Willstaetter's experiments with the carotinoids have made possible the separation of the individual components of this group.

Industrial Accident Boards and Commissions—The annual convention of the International Association of Industrial Accident Boards and Commissions will be held at the Congress Hotel, Chicago, September 11-15. Wednesday, September 13, will be devoted entirely to medical and surgical subjects by the following Chicago physicians:

Nathan S. Davis, III, "Difference Between Backache Due to Trauma and That Due to Disease."

John D. Ellis, "Routine Examination of the Injured Back."

Paul B. Magnuson, "Congenital Anomalies and Arthritis as Contributing Causes in Injuries of the Spine."

Hollis E. Potter, (1) "The Wedge Shaped Vertebra," (2) "Some Distinctions Between Healed Fractures and Healed Vertebral Disease."

Claude R. G. Forrester, "Reduction of Disability by Fusion of Vertebrae After Back Injury."

Philip H. Kreuzer, "Shortening the Period of Disability After Fractures of the Spine."

LeRoy P. Kuhn, "Final Disposition of Back Injury Cases."

Vaccination Defined—The scarification of an arm and the introduction of vaccine virus do not constitute vaccination when immediately thereafter the vaccination wound is painted with tincture of iodine according to a decision of Justice Adkins of the Supreme Court of the District of Columbia. The laws of the district provide that no child shall be admitted into the public schools who has not been duly vaccinated or otherwise protected against smallpox. The parents of two children having failed to procure their admission into the public schools without vaccination took them to a physician to be vaccinated. After he had scarified their arms and applied the vaccine, he went into an adjoining room to make out the necessary vaccination certificates. On his return he found that tincture of iodine had been applied to the vaccination wound of one of the children. The father nevertheless petitioned the Supreme Court for a writ of mandamus to compel the super-

intendent of schools to admit the children. Justice Adkins held however that there had been no vaccination as required by law and dismissed the petition.

Pacific Northwest Medical Association—The annual meeting of the Pacific Northwest Medical Association will be held in Vancouver, B. C., July 4-7, under the presidency of Dr. Bertram D. Gillies, Vancouver. Guest speakers, each of whom will give several addresses and conduct clinics, include:

Dr. Alfred T. Bazin, Montreal, "Acute Osteomyelitis, Tumors of the Colon and Rectum and Lesions of the Breast."

Dr. Charles H. Best, Toronto, "Recent Work on Carbohydrate Metabolism, Fat Metabolism and Liver Function Tests."

Dr. William Boyd, Winnipeg, "Tumors of the Neck, Pathology of the Breast Regarded as Disordered Physiology and Recovery from Infection."

Dr. John G. Fitzgerald, Toronto, "Meningococci, Meningitis, Staphylococci, Infections and the Nature of Antigens."

Dr. Alvah H. Gordon, Montreal, "Migraine, Diagnosis of Disease with Coincident Enlargement of the Liver and Spleen."

Dr. Alvin T. Mathers, Winnipeg, "Medicolegal Problems, Psychoneuroses and Sleep and Its Disorders."

Dr. Samuel A. Kinnier, London, England, "Visceral and Affective Epilepsy, Cerebral Tumors and Hydrata from the Physiologic Side."

Dr. David E. S. Wishart, Toronto, "Vertigo, Mastoiditis in Children and Sinusitis in Children."

Medical Bills in Congress—Bills Introduced S 1831 introduced by Mr. Schall, Minnesota, H R 5866 and H R 5882 introduced by Representative Smith, Washington and H R 5908, introduced by Representative Gray, Indiana, propose to reenact all public laws granting medical or hospital treatment, domiciliary care, compensation and other allowances, pensions and retirement pay to veterans that were repealed by the Economy Act approved March 20, 1933. S 1842 introduced by Senator Hastings, Delaware, and H R 5978 introduced by Representative Pierce, Oregon, propose to authorize the dissemination of information relating to the prevention of conception, and articles, instruments, substances, drugs and medicines designed adapted or intended for the prevention of conception: (1) by any physician legally licensed to practice medicine or by his direction or prescription; (2) by any medical college legally chartered under the laws of any state, territory or the District of Columbia; (3) by any druggist in filling any prescription of a licensed physician or (4) by any hospital or clinic licensed in any state, territory or the District of Columbia. S 1944 introduced by Senator Copeland, New York, and H R 6110 introduced by Representative Sirovich, New York, propose to prevent the manufacture, shipment and sale of adulterated or misbranded food, drugs and cosmetics to regulate traffic therein and to prevent the false advertisement of food, drugs and cosmetics. H R 5851, introduced by Representative Miller, Arkansas, H R 5883 introduced by Representative Glover, Arkansas, and H R 5906, introduced by Representative Eltse, California, propose to amend the Economy Act so as to provide increased pensions for veterans. H R 5926 introduced by Representative Dingell, Michigan, proposes to amend the Reconstruction Finance Corporation Act to provide for loans to nonprofit corporations organized for the purpose of operating hospitals and homes for sick, infirm, indigent persons of old age. H R 5967 introduced (by request) by Representative Ludlow, Indiana, proposes to prohibit the counterfeiting of drugs. H R 6111 and H R 6118, introduced by Representative Sirovich, New York, propose to provide for the truthful labeling of drugs.

FOREIGN

Prize for Essay on Industrial Accidents—The International Congress for Industrial Diseases and Accidents has instituted a prize of 1000 Swiss francs for the best essay on the consequences of an industrial accident. The manuscript, which may be in German, French, Italian or English, should be sent to the general secretary of the congress, Geneva, before December 1931.

Society News—The sixth English-speaking Conference on Maternity and Child Welfare will be held in London, July 5-7. Sir George Newman, medical officer of health of Great Britain, will deliver the presidential address. Among subjects to be discussed are scope and advancement of antenatal care, care and protection of illegitimate children and health of the child in relation to environment. For information apply to Miss J. Halford, 117 Piccadilly, London, W. 1.

Course for Otolaryngologists—The Association of Lecturers for Medical Post-Graduate Courses in Berlin is sponsoring an intensive graduate course for otolaryngologists in English, at the University of Berlin, July 24-August 4. The number of participants is limited to fifteen as practical work will be emphasized. For all further information apply to the secretary, English section, Dozentenvereinigung für Ärztliche Fortbildung, Berlin, N. W. 7, Robert Kochplatz 7.

Institute of Hygiene Opened in Calcutta.—The All-India Institute of Hygiene and Public Health, Calcutta, a gift of the Rockefeller Foundation to the government of India, was opened recently, addresses were made by Sir John Anderson, governor of Bengal, and Lieut. Col Alexander D Stewart, director of the institute. The school will be operated in cooperation with the Calcutta School of Tropical Medicine, where basic subjects will continue to be taught, while the institute deals purely with public health subjects related to Indian requirements. It will later be affiliated with the University of Calcutta, through which a doctorate in public health will be offered. The building, which harmonizes with the school of tropical medicine, has four stories, with facilities for teaching, laboratory work and lectures. A number of rooms will be artificially cooled.

Government Services

Army Personals

Major Joseph C. Brething relieved from duty at Chilkoot Barracks Alaska and assigned at Fort Banks, Mass.

Major John Wallace, relieved at Walter Reed General Hospital and assigned to the Hawaiian Department.

Lieut. Col Frederick S. Wright, on completion of present tour of foreign service is assigned at Fitzsimons General Hospital Denver. Col Robert H. Pierson was to proceed to his home, Dec. 26 1932 to await retirement, for the convenience of the government.

Lieut. Harry B. Ditmore, Major William K. Evans, Major Ralph Duffy and Col. Leartus J. Owen having been found incapacitated for active service on account of disability incident thereto their retirement is announced.

Col Lucius L. Hopwood, Major William E. McCormack, Major Fielding T. Robeson and Col Peter C. Field having been found by an army retiring board incapacitated for active service on account of disability incident thereto their retirement is announced.

Changes in Veterans' Administration

The following changes in the medical personnel of the Veterans' Administration, among others, were reported in the April issue of the *Medical Bulletin*:

Dr. Nathaniel H. Badames reinstated at Bronx N. Y.
Dr. Martin L. Black reinstated at Bronx N. Y.
Dr. Robert H. Christian to regional office Birmingham Ala.
Dr. Grover C. Daniel to Veterans Administration Home Los Angeles
Dr. Joseph P. DeRiver reinstated at Bronx N. Y.
Dr. Wallace A. Gerrie reinstated at Columbia S. C.
Dr. Silas R. Hosmer to regional office Cincinnati.
Dr. Irving I. Ludwig to Canandaigua N. Y.
Dr. Charlie M. Mathias to Aspinwall Pa.
Dr. Harry Moskowitz to Bronx N. Y.
Dr. Gilbert A. Rhodes to Tuscaloosa, Ala.
Dr. Harold E. Schwing to Aspinwall Pa.
Dr. Shelton G. Silverburg to Canandaigua N. Y.
Dr. Robert I. Souther reinstated at Bronx, N. Y.
Dr. Thaddeus S. Troy to Veterans Administration Home St. Petersburg Fla.
Dr. Oliver M. Warner to Aspinwall Pa.

U S Public Health Service

Passed Asst. Surg. (R) Floyd N. Shipp relieved at New London Conn. and assigned at the Marine Hospital Mobile, Ala.
Surg. (R) Carl B. DeForest, relieved at Mobile and assigned at the U. S. Coast Guard Academy New London Conn.
Passed Asst. Surg. Ralph Gregg relieved at Warsaw Poland and assigned at Genoa Italy.
Passed Asst. Surg. Gregory J. Van Beeck relieved at Genoa Italy and assigned at Ellis Island.
Passed Asst. Surg. Edwin G. Williams relieved at Liverpool England and assigned at Warsaw Poland.
Asst. Surg. Austin V. Deibert relieved at New Orleans and assigned at the penitentiary Atlanta Ga.
Passed Asst. Surg. Erval R. Coffey relieved at Washington D. C. and assigned at Seattle to establish headquarters for the purpose of cooperating with the state health department in the enforcement of its rules and regulations.
Surg. William A. Korn relieved at Port Arthur Texas and assigned to the Marine Hospital San Francisco for duty.
Surg. Herbert M. Manning relieved at Warsaw Poland and assigned to duty at Washington D. C.
Surg. Octavins M. Spencer relieved at Helena Mont. and assigned at the Marine Hospital Chicago.
Surg. John W. Tappan, relieved at San Diego on or about June 1 and assigned at El Paso Texas.

Courses for Flight Surgeons

Beginning with the next training year, the militia bureau will offer a program whereby six medical officers will be given active duty training at the School of Aviation Medicine. Two six weeks courses will be conducted, one beginning October 15 one March 1, each year. Aptitude for service will be of foremost consideration in the selection of the officers to take the course.

The Resignation of Sir Arthur Keith

After twenty-five years' work as conservator of the Museum of the Royal College of Surgeons and as hunterian lecturer, Sir Arthur Keith, who is 67 and has been in poor health, is about to resign. To all who know the college the loss will be considered irreparable. A specialist in many subjects—anatomist, physiologist, pathologist, anthropologist—he has, perhaps for this reason, none of the specialist's narrow outlook. Indeed, the delight of his teaching is the philosophic breadth with which he views every subject. The museum of the college has the greatest collection in the world illustrating the phenomena of life, in both health and disease, and is an expansion of the famous collection of John Hunter. His work and teaching are so much in evidence that the college might be described as a temple devoted to his memory. To no living man can the great adjective hunterian be applied with the same force as to Keith. Indeed, in this age of specialists he may be described as the last of the hunterians. All who have heard him lecture will recall how he loved to show that some recent advance had been foreshadowed in Hunter's teaching even the doctrine of evolution. Evolutionist is the word that best sums up Keith who has said that if he had to edit "The Origin of Species" he would find nothing to erase but much new evidence to add. His teaching is permeated with evolution.

But Keith is not severing his connection with the college. He will have charge of the two laboratories of the college recently built at Downe, in Kent, where Charles Darwin lived. They are endowed by Sir Buckstone Browne, a retired genito-urinary surgeon and are for experimental work in surgery. Keith will supervise the work of the young surgeons who will live and work in Downe.

Assistance for Professors Displaced in Germany

An organization called the Academic Assistance Council is being formed to assist teachers and investigators who "on the grounds of religion, political opinion or race are unable to carry on their work in their own country." An appeal issued to all "concerned for academic freedom and the security of learning" states that eminent scholars, men of science and university teachers are being compelled to relinquish their posts in German universities. Outside help for more than a small fraction of teachers now likely to be condemned to want and idleness, will depend on the existence of large funds specially devoted to the purpose. Some organization will be needed to act as a center of information and put the teachers concerned into touch with the institutions that can best help them. A provisional council has been formed for these purposes, which will cooperate with similar organizations now being formed in other countries. Means are asked to prevent the waste of exceptional ability. It is pointed out that the issue raised is not a Jewish one alone, many who have suffered have no Jewish connection. The Royal Society has placed accommodation at the disposal of the council. Sir William Beveridge and Prof. C. S. Gibson are acting as honorary secretaries. The appeal is signed by the most eminent British scientists, such as Lord Raveleigh, Lord Rutherford, Sir J. J. Thompson and Sir William Bragg. The scientific side of the medical profession is represented by Professors J. S. Haldane, Sir Gowland Hopkins, Sir Charles S. Sherrington, A. V. Hill, G. Elliot Smith and Major Greenwood. The names are given of 164 teachers named in German newspapers as having been given leave of absence, been dismissed or having resigned as a protest against other dismissals or action of students between

April 4 and May 15. The list is confined to institutions of a university character and includes professors and privatdozenten but not assistants engaged in research work. The great bulk of the persons named are professors. It is known that the list is incomplete but it has been thought best to rely only on statements that have become public in Germany and so far have not been contradicted.

International Pediatric Conference

The third International Pediatric Conference will be held in London at the House of the British Medical Association, July 20, 21 and 22, under the presidency of Prof. G. F. Still. The congress will be opened by the Duke and Duchess of York who will welcome the members in the great hall of University College. The subjects for general discussion include the nature of allergy and the prophylaxis of milk borne diseases. Nominations are invited from the secretaries of the various national committees for delegates to take part in these discussions and to contribute independent papers. Membership in the conference is open to all members of a recognized medical society, but they must be nominated by their own national committee. The subscription for members is \$10 and for nonmedical persons accompanying members \$5 payable in advance to Dr. James H. Thursfield, 84 Wimpole Street, London W. 1. A demonstration of patients from all the children's clinics in London will be given at the Hospital for Sick Children, Great Ormond Street. The secretary is Dr. Leonard Findlay, 61 Harley Street, London, W. 1.

Controversy Concerning the Nature of Bacteriophage

The discovery of d'Herelle concerning the existence of filtrable and living viruses that develop in bacterial cultures and are capable of producing bacteriolysis has always been the subject of controversies at the Institut Pasteur de Paris, where d'Herelle made his discovery. The clinical results are incontestable, but d'Herelle regards this lyzing principle as a living micro-organism, which he calls 'bacteriophage,' and supports his view on the fact that this principle can be cultivated indefinitely by transplanting in nutritive mediums and on the added fact that it is destroyed by heat. Innumerable observations have shown that the bacteriophage of the staphylococcus, when injected into the lesions of furuncles or anthrax, renders the pus sterile. The bacteriophage of cholera, when implanted in India in the wells of infected regions, has promptly arrested epidemics. Nevertheless, Professors Roux and Calmette, the directors of the Institut Pasteur de Paris have always questioned the living nature of the bacteriophage. That is why d'Herelle who is of Canadian origin left the Institut Pasteur, a few years ago and went to Brussels at first to work with Bordet and later to Alexandria where the government put him in charge of the laboratory of the sanitary services and sent him on a mission to the Indies. A new fact has been developed that appears to justify the opinion of the Institut Pasteur. Mr. Calmette has recently presented to the Academy of Sciences the results of research by Noel Bernard and Guillemin who have found, in cultures of the cholera vibrio, a precipitable diastase that has the power of rapidly lyzing the vibrio. This diastase, which may be destroyed by heat, acts in infinitesimal doses and makes indefinitely active the tubes of physiologic solution of sodium chloride into which it is successively introduced as in the transplantations of a bacterial culture. It appears, therefore, to undergo a development, an observation that is new in the history of ferments and that is fraught with great consequences in biology. Further research is necessary, but, from present indications, Mr. Calmette thinks

that he is justified in concluding that the bacteriophage, as he has always suspected, is a myth.

Neutralizing Properties of Blood Serum of Adults Toward Poliomyelitis Virus

Netter, Levaditi and Hornus have contributed research on the neutralization of the virus of poliomyelitis by the blood serum of adults who have lived with patients with poliomyelitis. During the epidemic, two years ago, in Alsace, which spread over the eastern provinces of France, Levaditi was delegated by the minister of public health to make an extensive inquiry. He conceived the idea that possibly the physicians and nurses might be playing the part of germ carriers, for poliomyelitis appeared in homes soon after they had been present because of other diseases. These germ carriers were immunized without knowing it. It was assumed that they had probably suffered an attack of the virus, which passed unobserved but which was sufficient to immunize them. It was shown that their blood serum was capable of neutralizing the virus or of making it harmless when injected into apes. Finally, it was found that this blood serum could be administered to sick patients with the same curative effects that the blood serum of convalescents from the disease was found to possess. Netter and Levaditi have announced to the Academy of Medicine that they tested the neutralizing power of the blood serum of fifteen normal adults residing where poliomyelitis had been present. This power was found in ten cases to be complete, in one case marked in two cases perceptible, and in two cases nil. Mr. Netter considers it probable that the presence of neutralizing substances in the blood should be attributed to a previous infection that passed unobserved. As the neutralizing power varies in different serums, it is advisable to mix several serums. They found that a mixture of the serum of three persons from Paris who had had no contacts with poliomyelitis patients neutralized the virus at the same dilution as the mixture of three persons residing in Le Mans who had had prolonged contacts with poliomyelitis patients. Netter adds that it is advisable to determine in advance the neutralizing power of the serum of professional donors of blood for transfusion, so as to be in a position to secure at once from them serum that would be active against poliomyelitis, in case of an emergency.

BERLIN

(From Our Regular Correspondent)

May 22, 1933

The Surgical Congress

The fifty-seventh annual session of the Deutsche Gesellschaft für Chirurgie was held as usual in Berlin, immediately after Easter. The opening address was delivered by the president, Prof. W. Roepke, director of the Wuppertal-Barmen Municipal Hospital, who referred to the national celebration and took a strong stand against the breaking up of medicine into an undue number of specialties. He said that for the progress of surgery it was indispensable to protect it against further splitting off of specialties, since only the surgeon with knowledge of the manifold connections and relationships between the organs of the body could be an exponent of real surgery. Such branches as orthopedics and the treatment of accidents should not be separated from general surgery. He pointed out what had been accomplished in recent years in the various fields of surgery. Surgery of the extremities, which, because of the increase in accidents, made increasing demands on surgical skill, must be placed in the foreground of surgical instruction. In the treatment of injured persons, the psychic rehabilitation of the patient so that he may resume his place in the world must receive consideration.

OPERATIVE SHOCK

Rehn, ordinarius at the University of Freiburg, presented a comprehensive paper on "Operative Shock." A distinction must

be made between a purely psychic and injury shock, and shock due to operations. The severe psychic disturbances that formerly resulted from surgical interventions have been almost eliminated through the improvements in the administration of anesthetics. It is now regarded as one of the chief tasks of preparation for an operation to provide all possible means for the prevention of psychic shock. Operative shock affects solely the vegetative system, which, as a result of the anesthesia, is much reduced in its susceptibility. Nevertheless, owing to vagus irritation, excitation in the coronary vessels may develop. The principal effects concern no doubt the central nervous system and the vascular system. Operative shock varies with the site of the operation. A deeper biologic insight into the connections between these events will make a better surgical performance possible. Hence, a precise understanding of the susceptibility to shock is important. This susceptibility expresses itself to a greater extent as circulatory disturbance than as collapse. The conditions designated by Rössle as allergic disturbances play a special role in this connection. But the formation of histamine has nothing to do with operative shock as such. It is more likely that the collection of large quantities of blood in the damaged musculature plays a role. Every successful operation constitutes a performance of the body. The decrease in the circulatory volume of the blood and the diminution of the minute volume are in direct relation to the effort put forth by the body and to the volume of work forced on it by the operation. The keeping of both in an optimal condition requires a commensurate preparation for the operation.

During the discussion, Rehn's assistant, von Brandis, called attention to the results of his research as showing the practical importance of the influence of anesthetics on the effects of remedies used to control the circulation. Frequently the circulation is damaged by the operative shock and hence is more likely to need active support. The discovery of the reduced action of these remedies as a result of anesthesia is of especial importance for the surgeon because he is inclined to have too much confidence in the effectiveness of long recognized remedies for the circulation or to prescribe them in too small amounts or too weak concentrations. Special attention was called to the favorable postoperative action of papaverine on the peripheral arterial circulation for the relief of spasm and consequent disappearance of cyanosis. Klapp, surgeon, of Marburg, combats fat embolism in a drastic manner by standing his patients on the head and thus causing a migration of the fat emboli into the harmless periphery.

Professor Gauss of Würzburg emphasized that the dangers arising from the explosion of anesthetics are greater than is generally known. In using the ordinary large apparatus for the administration of anesthetics, electrical charges up to 5,000 volts quickly develop and a short circuit may be caused by a mere touch. This danger can be avoided with certainty by seeing to it that all apparatus is properly grounded.

As is the custom the congress set apart an evening for the presentation of photographs, at which time Henschen of Basel displayed his roentgenospectroscopic researches on diseased bones and on callus. Hintze of Berlin gave film presentations of healed cases of cancer of the mucosa and the internal organs, derived from the extensive material of the Bier clinic.

The second topic, "Internal Injuries of the Knee Joint," was presented by Bircher of Aarau, who brought out the interesting fact that the reconstruction of a healthy knee joint in men of the plains and in men of the highlands shows essential differences. He gave the results of his observations in 1,000 knee joint operations. The results of the substitution of kangaroo tendons for lacerated crucial ligaments were excellent.

The second day of the congress was devoted to the treatment of fractures. Magnus, the director of the large Miners' Hospital in Bochum, offered a communication on "The Indications and Contraindications in the Treatment of Fractures." In

1932, 4,500 fractures were treated in his hospital. With the aid of photographs, Magnus showed the results that he had secured with simple equipment, since general practitioners and small hospitals do not have at their disposal the apparatus found in large hospitals. In his environment it is desirable also to get along with as simple procedures as possible, in order that imposing methods may not increase immoderately the patient's consciousness of being a patient. Hence, the more simple the method, the better the treatment. Numerous details in the treatment of fractures were discussed on the basis of wide experience. Magnus does not favor the suggestion that persons injured in accidents should be treated in special hospitals for such cases. A better plan would be to provide, by means of continuation courses such instruction as would make all physicians familiar with the most suitable simple methods.

OPERATIVE TREATMENT FOR CANCER

"Criteria for the Operative Treatment of Cancer" was the topic selected by Prof. F. König, surgeon, of Würzburg. He emphasized that, owing to a publicity campaign, the view had been spread that operations for cancer were almost never successful and had no particular value. He cited statistics from hospitals in southern Germany to prove that the number of cured cancer patients runs up into the hundreds and that not only five years has passed without recurrence since the operation but in many cases, even ten, twenty and more years. These statistics deal, in part, with especially malignant tumors. In contrast with a recent book by Liek, König said there is no doubt that surgical treatment of cancer, in combination with irradiation, produces much better results than Liek is willing to admit. He urged that every operable cancer be subjected without fail to surgical treatment. The only exception would be cutaneous and mucosal cancers, provided they are easily accessible. Schmieden of Frankfurt-on-Main likewise held this view as representing the uniform opinion of German surgeons. Schönbauer of Vienna, who recommended the use of the electric knife for biopsies, took the same stand.

The papers on "The Surgery of Accidents" were introduced by far reaching statements by Lexer of Munich, who said that the task of the surgeon does not consist merely in eliminating the injury, a much more important task is to restore completely the working capacity of the injured person, and for that purpose psychic supervision is imperative. Such supervision cannot be successfully exercised by any one other than the physician, and the best person for the task is the surgeon who performed the operation, because the patient has learned to trust him. Measures introduced with that in view have been successful at the university clinic of which Lexer is the director.

"The Catgut Problem" was elaborated by Konrich of Berlin and Zeissler of Altona. In parallel investigations, many thousand meters of catgut from various German and foreign pharmaceutical houses were examined. The results were not absolutely satisfactory, so that, in collaboration with the federal bureau of health, the Deutsche Gesellschaft für Chirurgie and the catgut industry, a center for the examination of catgut is to be created, which will study the problem of the production of sterile catgut.

Professor Kirschner of Tübingen was chosen president of the society for the 1934 session.

Unauthorized Traffic in Drugs

For decades, the German Reich has had regulations governing the traffic in drugs and medicaments. In a recent circular letter from the Prussian minister of the interior it is said that the dispensing of drugs and medicines outside of the pharmacies has increased to an alarming extent. It has even been observed that remedies that are "subject to prescription" are sometimes sold over the counter in shops handling mis-

cellaneous articles. The ministry of the interior has therefore issued instructions to the authorities to take drastic action to check this unauthorized traffic in drugs.

Treatment of Cancer of the Cervix

Addressing recently the Societe belge de chirurgie Delporte, Cahen and Sluys gave a clear account of the present status of the treatment of cancer of the cervix uteri. They show that there are differences of opinion, owing to the fact that the classification of cases as proposed by the cancer commission of the League of Nations has only a relative character. The personal factor plays a great part in the estimation of operability. The operative statistics are also sometimes purposely distorted.

The Wertheim operation has given remarkable results, but it is applicable to only a small number of cases. The inoperable cases are numerous and depend much on the person who makes the selection. The operative results likewise vary. The operation has a high mortality, although it has been diminished, especially since the use of Mikulicz drainage. The results from current practice are, however, much less brilliant than some published statistics would indicate.

The technic of the application of curietherapy is simple, whereas the Wertheim operation requires long experience. The results are better than with the Wertheim operation for one obtains 45 per cent of recoveries at the end of five years. Curitherapy has one disadvantage: the operator cannot so carefully treat the glands, and it sometimes happens that a recurrence develops.

That is why the authors supplement curietherapy with a Wertheim operation, which is performed from two to three months later. The operation is then performed without difficulty. Among fifty-three cases in which they operated under these conditions, the authors had three deaths, one due to embolism on the third day, and the two others due to generalized peritonitis. In nine of the specimens of tissue removed cancer cells were found, enveloped in fibrous tissue. Fifteen of the fifty-three patients operated on had glands containing cancer cells.

They reported also the results secured by means of curietherapy during the previous ten years. They applied this treatment in 437 cases without taking account of operability. The treatment was applied in two stages, a vaginal application being followed by an intra uterine application after dilation. In some patients the treatment was supplemented by intra-abdominal applications. They reported eighty recoveries out of 327 cases (26 per cent), after an interval of five years. The recurrences took the form of a progressive invasion of the pelvis which shows that the action of the rays on the glands had been inadequate.

Rapid Transportation of Patients

Toward the end of 1932, the Red Cross Society of Belgium organized in Belgium twenty-seven centers of sanitary transportation. Thirty-nine vehicles have been constantly in service and more than 10,000 sick and injured persons have had the benefits of this service. The transport centers are located so that no town is more than twenty-five miles distant from a center. This system fulfils perfectly its essential purpose of giving to patients first aid on the spot and of transporting them immediately and under the best conditions to a hospital center.

Eradication of Mosquito Larvae at Elisabethville

The Societe belge de medecine tropicale has published a report on the activity of its sanitary crew in Elisabethville during the first six months of its existence. The crew removed 28,043 empty receptacles (tin cans and the like) from the city and the

environs. 3,084 hatching places of mosquitoes were destroyed. In general, the European quarters of the city are less sanitary than the native quarters, and the servants of the Europeans are responsible for these conditions. The report emphasizes the need of cleaning up the neutral zone between the European and the native quarters.

The First Necropsies in Vienna

During a lecture recently delivered at the Historisches Seminar of the University of Vienna it was recalled that the first necropsy on a human body performed in accordance with scientific principles, within the area of German countries, occurred in Vienna in 1404. From Lower Italy, where every five years one necropsy on a human body was permitted by law, the art of anatomy spread through Upper Italy into Germany. Galeazzo de Sophia, a physician of Padua, brought this art to Vienna, where, on Feb. 12, 1404, in the presence of "doctors and scholars" of the medical faculty and of "surgeons and apothecaries," he performed a necropsy. The second dissection took place in 1418, and lasted from February 21 to February 28. After completion of the dissection, the bishop held a solemn mass for the soul of the deceased. In 1435, the students of medicine demanded that a public "anatomy" should be again undertaken during the winter semester and that henceforth a human body (alternately a male and a female body) should be dissected every year. The faculty accepted this suggestion and a committee of two doctors and two students was appointed in March, 1436, to make the arrangements. Dr. Johannes Eigel was chosen to serve as "demonstrator." But the corpse could not be secured. Four years later the students renewed their demand, and again the faculty complied but stipulated that only doctors and scholars would be permitted to be present. To secure a body, a petition was sent to the mayor and to the judge of the municipal court of Vienna requesting that the body of a criminal who was soon to be hanged should be placed at the disposal of the medical faculty, after execution of the sentence. The request was granted. But when the body of the hanged criminal was turned over to the students and dissection begun, the supposedly dead man showed signs of life. The circumstance caused so much excitement that the dissection did not take place. Not until four years later was the desire of the students fulfilled. The records of the fifteenth century reveal only two other necropsies performed in Vienna, one in 1452 and one in 1459, or a total of five. In the next century, however, more frequent opportunities to study the structure of the body by means of necropsies were afforded.

Pathogenesis of Acute Disorders of the Pancreas

Research at the Chirurgische Klinik of the University of Vienna on a large number of patients, concerning which Dr. H. L. Popper reported recently before the Gesellschaft der Aerzte, yielded data on the pathogenesis of acute pancreatitis which in recent years has become prevalent. A distinction is still made between pancreatitis and pancreatic necrosis. The former is regarded as a bacterial disorder, whereas the necrosis is interpreted as a result of an activation by trypsin, which is brought about by the flow of bile into the pancreas.

In 200 gallbladders that came to operation, increased ferment values were found on examination to be present in the bile having been produced by the penetration of pancreatic fluid from the pancreatic duct into the common bile duct. Further observations showed that in the majority of cases of acute pancreatic disorders such an influx of pancreatic fluid actually occurs. There develops in the biliary passages a primary

trypsin activation, and this is carried into the pancreas from the distal portion of the choledochus within the pancreas. Whereas normally the flow of pancreatic fluid into the biliary passages takes place without further incident, since the mixture rapidly flows out again, in the event of disturbances of the outflow at Vater's papilla there occurs an intensive interaction of bile and pancreatic fluid on each other and a marked action on the adjacent tissues. The disturbance of the outflow is caused usually by stone but occasionally also by spastic conditions affecting Oddi's sphincter. This conception of the origin of acute pancreatic disorders corresponds to the measurements of the pressure in the pancreatic and the bile ducts and is doubtless correct for the majority of cases—also for the majority of postoperative cases of pancreatitis. In the possibility of communication between the choledochus and the pancreatic duct lies the factor that predisposes to pancreatitis. Dr Popper rejects an etiologic separation of pancreatitis and pancreatic necrosis. He thinks that the prevailing condition of the pancreatic secretion is the most important factor determining the type of disorder that arises. It is his opinion also that experimentation on animals is not conclusive for the judging of such conditions. Direct observation on man is required for the reason that in animals the conditions about the mouth of the pancreas are entirely different from those found in man.

Eosinophilia in the Child

In the *Medicinisches Seminar*, Dr Lehnendorff discussed recently eosinophilia in the child. He emphasized that this condition in itself justified no far-reaching conclusions. The most important thing is a careful clinical examination of the patient, but the discovery of an eosinophilia contributes, to be sure, much toward the clarification of the case. It is known that the spleen regulates in some manner, possibly by means of hormones, the production and distribution of acidophil cells in the blood. It may also be stated with certainty that the eosinophils constitute an excellent reagent in the child for infections and intoxications, as they disappear from the blood when the infections appear. Reappearance of the eosinophils may be regarded as a favorable prognostic sign. This 'post-infectious eosinophilia' amounts usually only to from 5 to 8 per cent, but it is diagnostically and prognostically very significant. For example, it announces the approaching lysis and cure of pneumonia, even though the infiltration symptoms are still intensive. Conversely, absence of eosinophilia after the drop in temperature justifies the suspicion that it was only a pseudocrisis. The prognostically favorable significance of eosinophilia holds good in all infectious processes such as sepsis, suppurations and osteomyelitis. Also in chronic diseases such as tuberculosis, it is valuable. If, in the presence of acute exanthems, there is some uncertainty as to whether rubella, scarlet fever or a scarlatiniform exanthem is involved, eosinophilia will decide in favor of scarlet fever. The phenomenon is here sharply marked. Also in allergic disorders it appears distinctly in asthma, hay fever, urticaria, migraine and idiosyncrasy of various kinds. But also a number of medicaments, such as digitalis, produce occasionally considerable eosinophilia. In the frequent severe abdominal conditions, which in childhood so often cause the examiner to suspect appendicitis or peritonitis, the acidophils point away from an inflammatory genesis. Since all worm disorders are associated with eosinophilia (*Oxyuris*, *Ascaris*, *Trichomonas* moderately, *Echinococcus* much more so, but especially *Trichinella*—50 per cent or more), such a condition must be suspected in dealing with children. Also prurigo pemphigus, herpes-dermatitis and itching eczemas, likewise all forms of medicine dermatitis as well as lymphogranulomatosis show higher values of eosinophilia. Abnormally high values (from 30 to 90 per cent) are found in the condition designated splenomegalia with persistent eosinophilia' with a very large hard spleen also after

a liver diet, particularly after the ingestion of raw liver but not after liver extracts. It is not found until from three to six weeks after the beginning of the liver diet. It is not characteristic for pernicious anemia but arises in every anemia, also in absolutely healthy persons if they follow a liver diet long enough, and attains fairly high values 60 per cent or more. This 'alimentary eosinophilia' may cause diagnostic errors, if the examiner loses sight of it.

A New Cancer Hospital in Vienna

Vienna possesses at present only one institute that deals exclusively with research and treatment of cancer. The hospital owes its existence to a generous gift of an American philanthropist who, in gratitude for his recovery from a grave disease, supplied his Vienna physician with the funds for this institute. But recently, at the annual session of the Oesterreichische Gesellschaft für Krebsforschung, Professor Eiselsberg announced that another American has made a large gift to be used for the erection of a second cancer hospital in Vienna. The institute will begin its work by the end of June this year. Prof. Dr Freund, who by his researches in this field has achieved international fame (the Freund-Kaminer reaction, the Freund diet), will become the director of the new hospital and is planning to test thoroughly the dietetic treatment of cancer disease. The new hospital will have twenty beds, together with the necessary laboratories and operating rooms. It is designed for patients of moderate means, the charges being the same as in all the public hospitals of Vienna.

Through the cooperation of the ministry of health, the sanitary department of the city of Vienna and the Gesellschaft für Krebsforschung und Bekämpfung, a census of all tumor patients in Vienna is contemplated, in order that a system of aid may be worked out. A beginning of a system of aid for cancer patients in Vienna has already been made through the creation of the excellent radium department in the Vienna Municipal Hospital where the surgical department has reserved sixty beds for the application of ray treatment in cancer, and where the records of all known cancer cases, their postoperative course and their precise control are thoroughly organized.

Surgical Treatment of Syringomyelia

The treatment of syringomyelia proposed by Poussep in 1927, which consisted in an attempt to relieve the spinal cord by an operative opening of the intramedullary cavities, has been tested in about fifty cases of syringomyelia. The results cannot be regarded as perfectly satisfactory, since the time has been too short and the number of cases too small. The assumption that the cavities in the spinal cord exert a pressure on the cord does not appear to be justified in all cases, as Professor Denk stated recently in an address before the Gesellschaft der Wiener Aerzte. He brought out that frequently one finds cavities without much rigid tension. Nevertheless, when these cavities were opened nearly always a marked improvement of the clinical symptoms followed. Professor Denk discussed the technic of the operation. The spinal cord is split longitudinally in the region of the cavity formation for a distance of from 1 to 3 cm, so that the content of the cavity is evacuated and can continue to escape through the incision. For the incision a spot in which the fluid is near the surface should be chosen. The dura and the soft parts are then sutured. How long the incision remains open is not yet known exactly. In one case, which resulted fatally four weeks after the operation, the wound was still open. Some German authors who have reported good operative results have emphasized that the wounds in the spinal cord apparently do not close. Professor Denk presented two cases, a man aged 47 and a man aged 54 in whom all previously known methods of treatment, including roentgen rays, had been fruitless. Incision of the spinal cord so far as the short period of observa-

tion permits an opinion at least checked the process if it did not cure the disorder. Soon after the operation (from six to ten days) a distinct diminution of the associated pain and spastic paresis was evident. It must be admitted, however, as was emphasized during the discussion, that likewise roentgen irradiations of such processes not infrequently bring about a marked retrogression of the subjective symptoms. In syringomyelia, young tissue that is highly sensitive to irradiation is involved for the most part especially the endothelium of the capillaries is damaged and thus the production of immoderate fluid is checked. If roentgen therapy proves ineffective an operation is in order and in many cases can be expected to yield fairly good results.

MADRID

May 3, 1933

International Congress of Ophthalmology

The fourteenth International Congress of Ophthalmology was held April 16-22 at Madrid with more than 2000 ophthalmologists from several countries in attendance. The president of the republic and the most prominent members of the government attended and delivered speeches. The official topics were tuberculosis of the iris and of the ciliary body and detachment of the retina. Following are abstracts of the discussions.

Dr E. V. L. Brown of Chicago said that the treatment of tuberculous iridocyclitis is not satisfactory from either the theoretical or the practical point of view. Roentgen therapy and the introduction of the patient's own blood into the anterior chamber of the eye, which have been considered the most effective treatment, fail to prevent recurrences and the appearance of the disease in the normal eye and they have no influence on the primary seat of the tuberculosis in the thorax. Exactly the same unsatisfactory results are observed with tuberculin therapy. The speaker recommended fresh air, rest and proper diet in order to improve the general condition of the patient as coadjuvant measures.

Dr Josef Igersheimer of Frankfurt-on-Main spoke on the pathologic anatomy of tuberculosis of the iris and of the ciliary body. He said that in some cases the tissues do not undergo a specific histologic reaction to the tubercle bacillus. He classified the clinical forms of tuberculosis of the iris and of the ciliary body into two groups. The first group is divided into two subgroups. The first subgroup, which includes the acute and subacute cases, is made up of certain forms of iridociliary tuberculosis characterized by the presence of either large or small nodules. The second subgroup, which includes the chronic cases, is made up of transitional forms with tuberculous lesions in the bulb without lesions in the uveal tract, forms with a suspected tuberculous structure of the uveal tract, forms of clinical tuberculosis of the uveal tract without specific histologic lesions, and forms with chronic inflammation of the uveal tract in which neither clinical nor anatomic signs of certainty of tuberculosis exist. The second group is made up of the forms in which the predominant symptom is either necrosis or diffuse suppuration. The more sensitized the tissues are, the more frequent the development of hypopyon, of caseation and of perforation of the bulb. These violent reactions are frequently observed in children. The conditions of immunity are important in the understanding of these forms, but at present and having only the results of the tuberculin reactions to go by, it is not possible to draw conclusions on the sensitization of the iridociliary tissues.

Dr H. Lagrange of Paris spoke on the differential diagnosis of tuberculosis of the iris and of the ciliary body. There are several clinical forms of exudative tuberculosis of the iris and of the ciliary body. The diagnosis of tuberculosis of the iris and of the ciliary body is difficult, especially when certain forms of iritis or iridocyclitis are present. The differential

diagnosis is made between tuberculosis, focal infection and syphilis. In cases in which neither a syphilitic etiology nor the presence of a focal infection can be proved, a diagnosis of tuberculosis is probably correct. It is a diagnosis of probability because there are no specific clinical signs to prove the presence of tuberculosis, except for the tuberculin test, which is still the most useful diagnostic method. The local prognosis of this type of tuberculosis is serious in the grave forms. Certain forms of fibrous tuberculosis associated with fibrous manifestations of general tuberculosis may present local and general variations, parallel to those of allergy.

Dr Arruga of Barcelona spoke on the etiology and pathogenesis of detachment of the retina. Two thirds of the cases occur in males, and bilateral detachment is frequently observed. In a group of 45,000 patients with eye diseases, 682 had retinal detachment and in 121 the lesion was bilateral. Myopia existed in 50 or 60 per cent of the cases of detachment of the retina. The choroid is torn more frequently than the retina, but it is not detached. Work in which the eyes are used to a great extent has not much influence as a causal factor. Histologic study proves that in most cases of retinal detachment there are atrophic changes with vascular degeneration of the retina. The intra-ocular pressure diminishes shortly after the detachment has occurred. The albumin content of the subretinal fluid increases as the detachment becomes older. It disappears, however, in very old detachments, probably because of the atrophy of the choroid. The specific gravity of this fluid is greater in the older than in the newer cases. Experimentation shows that the tearing of the retina either retards or prevents the reapplication of the detached retina. The theory of the choroidal exudation holds true in the pathogenesis of detachment of the retina in those cases in which the detachment is due to nephritic retinitis, exudative choroiditis and orbital diseases. When the detachment is caused by exudation, the retina may reapply itself if the exudates are reabsorbed. This is what happens in cases of retinitis complicating pregnancy. The theory of the retraction of the vitreous body seems logical when there are either vitreous hemorrhages or loss of the vitreous humor, because, during their reabsorption, retractile and cicatricial adhesions are formed. This theory, however, loses a great part of its value if one considers the absence of retinal detachment in the aged, following removal of a cataract or of the vitreous body, by Zur Nedden's method. The reapplication of the retina to the superior part of the detachment in cases in which a superior detachment becomes an inferior one shows also the lack of truthfulness of the theory of the retraction of the vitreous body. Dr Arruga believes that idiopathic detachment of the retina is due in most cases to a lesion in the retina itself. If the retina is normal and healthy it is not easily detached, even if it is torn. In the production of retinal detachment there are several factors involved that is, an energetic action of the vitreous body and the choroid, and some special condition in the retina itself. Experiments have shown that in order to cause detachment it is necessary to provoke large tears in the retina, a total withdrawal of the vitreous humor or an intense irritation of the choroid, and even in these conditions the detachment may be cured. The numerous retinal changes in the aged which are invisible in ophthalmologic examinations, as well as certain types of iridocyclitis which cannot be seen by direct examination of the eye but which can be discovered by the slit lamp may be made worse by the operation. Some nutritional disturbances and deficiencies of the liver and kidneys have an unfavorable action on the retina. Hypotension is due to the reabsorption of the vitreous humor by the choroid. It may be modified by psychic or moral disturbances and it favors detachment. Sclerosis of the retina favors detachment also in cases of small retinal tears. The form of the tear depends on the presence of adhesions between the

vitreous body, the retina and the choroid. The greater specific gravity of the subretinal fluid explains the progress of the detachment in a downward direction. It also justifies the position in which the patient is kept after the operation, that is, on the side on which the operation was performed.

Dr Giuseppe Ovio of Rome spoke on the history of the treatment of detachment of the retina. When the real pathology of the condition was still unknown, it was considered as a form of amaurosis in the correction of which medical treatment was resorted to. Ware proposed the puncture of the sclerotic coat to evacuate the subretinal fluid. Samelsohn in 1875 advised the application of a bandage causing compression in the eye while the patient was lying in dorsal decubitus. Nowadays, medical treatment is used according to Samelsohn's precepts. Besides that, several other measures such as having the patient in the dark, diaphoresis, the instillation of physostigmine and atropine, electrolysis, massage, the administration of iodine, mercurial and arsenical preparations, tuberculin therapy, a diet with little salt, and subconjunctival or intravitreal injections are used. The subconjunctival injections were recommended by Grosmann in 1883 although they became more widely used through the experiments of Mellinger in 1894. The foregoing measures are all based on logical conceptions. During the last half of a century there have been optimistic and pessimistic tides. Statistics presented by the author show that, under medical treatment, improvement occurs in 22 per cent of the cases and recovery in 22 per cent.

Dr Alfred Vogt of Zurich spoke on surgical treatment of detachment of the retina. Rest is such an important factor in treatment that alone it may accomplish the cure. The aim of surgical treatment of detachment of the retina is to close the tear. Galezowski was the first to perform systematic thermocauterization of the retinal tear as a treatment for detachment of the retina. Retinal perforation may be of traumatic origin. The so called spontaneous perforation of the retina may be favored by trauma in the presence of destructive processes of the retina, such as senile and presenile degeneration, myopic atrophy and cystic degeneration. The destruction of the vitreous humor parallels that of the retina. The spontaneous detachment is caused by either a tearing or a perforation. The hypotonia coexisting with the detachment is the result of the perforation and it disappears when the perforation is closed. To succeed in closing the perforation it is necessary to locate its origin, which may be done by ophthalmoscopic examination. Cauterization by using the apparatus of Gonin, electrocauterization, the chemical method of Guist, and diathermy according to the technic of Weve are the most important operative methods in use. The most simple method is ignipuncture by cautery and diathermy needle, which prevents loss of the vitreous humor. Cauterization with the needle should be exceedingly rapid (from one to three seconds). Otherwise serious injury may result. The author advised the use of the needle of Weve in cases of small perforations located near the choroid and the use of the galvanocautery in cases of extensive perforations near the ora serrata. Generally, two cauterizations are necessary to cure an extensive tear.

Trachoma and blindness were also discussed during the congress. Dr Wibaut of Amsterdam said that in 1931 an inquiry in which a great number of ophthalmologists from several countries took part was opened to study the initial symptoms of trachoma. It was found that in countries where trachoma is endemic the diagnosis is made long before the time of appearance of complications or scars. The difference of opinion among ophthalmologists rests on the fact that some of them consider certain cases as either benign or early forms of trachoma while others regard them as cases of follicular conjunctivitis. Most ophthalmologists, however, consider the early noncomplicated forms of trachoma highly important. These early forms are frequently observed in chil-

dren of preschool and school age. The author advised the systematic examination of children in school, at home and in the kindergarten in order to discover early cases of trachoma. These uncomplicated forms, if properly treated, may exist a long time without complications, even in those countries in which the virulent forms of the disease are not uncommon. The detection and treatment of trachomatous children are important in the campaign against trachoma. Instead of being sent away from school, trachomatous children should be treated in those educational centers.

Dr Riccardo Galeazzi of Rome presented statistical studies demonstrating the possibility of producing in the eye a local immunity by means of a polyvalent vaccine made with bacteria isolated from patients having different kinds of ocular infections. The author believes that trachoma is due to the association of bacteria superposed on a constitutional trachomatous substratum which is identified with adenoidism.

Dr P. K. Olitsky of New York reported the results of his experiments related with the transmission of trachoma from man to monkey. If the normal conjunctiva of monkeys is rubbed with secretions from trachomatous patients, or if monkeys receive a subconjunctival injection of trachomatous tissue of human origin characteristic granular conjunctivitis develops, and the disease may be transmitted from monkey to monkey. The speaker started a series of similar transfers with cultures of *Bacterium granulosis* obtained from human trachomatous material. The period of inoculation of the disease, the transmission of the infection from the inoculated eye to the normal one and the appearance, first, of the initial lesions and, later on, of the well developed lesions, as well as the histopathologic changes, are identical in animals in which the infection is transmitted by cultures and in those in which it is transmitted by infected tissues. The characteristic experimental lesions originate around the vessels, thus proving that the genesis of experimental trachoma is similar to that of human trachoma.

By the superposition of secondary infections in monkeys, following the inoculation with *Bacterium granulosis* it is possible to produce ocular lesions with a clinical aspect similar to that observed in florid trachoma in man. By the intracorneal injection of any agent with slight infective capacity, it is possible to produce in the animal a persistent keratitis similar to panus tenuis in trachoma in man. The active etiologic agent of these lesions is *Bacterium granulosis*. The intracorneal injection of these bacteria provokes the development of pseudopanulcus, which may persist at least for two years without regression of the lesions. The hypothesis that trachoma is a disease caused by an ultramicroscopic virus has not been as yet proved.

Dr Manuel Marquez of Madrid spoke on the necessity of making a rational classification of the causes of blindness and he presented a classification in the form of a chart.

At the closing of the congress a resolution was passed to be presented to the governments of several countries as a reaction of ophthalmologists against the charlatanism of those who sell eyeglasses or adjust them without being ophthalmologists. The congress moved that persons who sell glasses should do so only when they are prescribed by ophthalmologists, the only persons scientifically prepared to know the needs of their patients.

Loewenstein's Studies on Tuberculosis

Dr Ernst Loewenstein of Vienna recently lectured in the Escuela de Sanidad of Madrid on his studies on the tubercle bacillus. The culture is made in a nutritive medium of the yolk of egg, after the material under investigation has been washed in a 15 per cent solution of sulphuric acid. All bacteria except the tubercle bacillus are killed in the solution. The speaker is able to show the presence of characteristic colonies of tubercle bacilli, even to macroscopic examination in 80 per cent of the cases when the cultures have been made with the blood of tuberculous patients. Dr Loewenstein explained in

tion permits an opinion at least checked the process if it did not cure the disorder. Soon after the operation (from six to ten days), a distinct diminution of the associated pain and spastic paresis was evident. It must be admitted however, as was emphasized during the discussion that likewise roentgen irradiations of such processes not infrequently bring about a marked retrogression of the subjective symptoms. In syngonmyelia, young tissue that is highly sensitive to irradiation is involved, for the most part especially the endothelium of the capillaries is damaged and thus the production of immoderate fluid is checked. If roentgen therapy proves ineffective an operation is in order and in many cases can be expected to yield fairly good results.

May 3 1933

International Congress of Ophthalmology

The fourteenth International Congress of Ophthalmology was held April 16-22, at Madrid with more than 2,000 ophthalmologists from several countries in attendance. The president of the republic and the most prominent members of the government attended and delivered speeches. The official topics were tuberculosis of the iris and of the ciliary body and detachment of the retina. Following are abstracts of the discussions.

Dr E. V. L. Brown of Chicago said that the treatment of tuberculous iridocyclitis is not satisfactory from either the theoretical or the practical point of view. Roentgen therapy and the introduction of the patient's own blood into the anterior chamber of the eye which have been considered the most effective treatment, fail to prevent recurrences and the appearance of the disease in the normal eye, and they have no influence on the primary seat of the tuberculosis in the thorax. Exactly the same unsatisfactory results are observed with tuberculin therapy. The speaker recommended fresh air, rest and proper diet in order to improve the general condition of the patient, as adjuvant measures.

Dr Josef Igersheimer of Frankfurt-on-Main spoke on the pathologic anatomy of tuberculosis of the iris and of the ciliary body. He said that in some cases the tissues do not undergo a specific histologic reaction to the tubercle bacillus. He classified the clinical forms of tuberculosis of the iris and of the ciliary body into two groups. The first group is divided into two subgroups. The first subgroup, which includes the acute and subacute cases, is made up of certain forms of iridociliary tuberculosis characterized by the presence of either large or small nodules. The second subgroup, which includes the chronic cases, is made up of transitional forms, forms with tuberculous lesions in the bulb without lesions in the uveal tract, forms with a suspected tuberculous structure of the uveal tract, forms of clinical tuberculosis of the uveal tract without specific histologic lesions, and forms with chronic inflammation of the uveal tract in which neither clinical nor anatomic signs of certainty of tuberculosis exist. The second group is made up of the forms in which the predominant symptom is either necrosis or diffuse suppuration. The more sensitized the tissues are, the more frequent the development of hypopyon of caseation and of perforation of the bulb. These violent reactions are frequently observed in children. The conditions of immunity are important in the understanding of these forms, but at present and having only the results of the tuberculin reactions to go by, it is not possible to draw conclusions on the sensitization of the iridociliary tissues.

Dr H. Lagrange of Paris spoke on the differential diagnosis of tuberculosis of the iris and of the ciliary body. There are several clinical forms of exudative tuberculosis of the iris and of the ciliary body. The diagnosis of tuberculosis of the iris and of the ciliary body is difficult, especially when certain forms of iritis or iridocyclitis are present. The differential

diagnosis is made between tuberculosis, focal infection and syphilis. In cases in which neither a syphilitic etiology nor the presence of a focal infection can be proved, a diagnosis of tuberculosis is probably correct. It is a diagnosis of probability because there are no specific clinical signs to prove the presence of tuberculosis, except for the tuberculin test, which is still the most useful diagnostic method. The local prognosis of this type of tuberculosis is serious in the grave forms. Certain forms of fibrous tuberculosis associated with fibrous manifestations of general tuberculosis may present local and general variations, parallel to those of allergy.

Dr Arruga of Barcelona spoke on the etiology and pathogenesis of detachment of the retina. Two thirds of the cases occur in males, and bilateral detachment is frequently observed. In a group of 45,000 patients with eye diseases, 682 had retinal detachment and in 121 the lesion was bilateral. Myopia existed in 50 or 60 per cent of the cases of detachment of the retina. The choroid is torn more frequently than the retina, but it is not detached. Work in which the eyes are used to a great extent has not much influence as a causal factor. Histologic study proves that in most cases of retinal detachment there are atrophic changes with vascular degeneration of the retina. The intra-ocular pressure diminishes shortly after the detachment has occurred. The albumin content of the subretinal fluid increases as the detachment becomes older. It disappears, however, in very old detachments, probably because of the atrophy of the choroid. The specific gravity of this fluid is greater in the older than in the newer cases. Experimentation shows that the tearing of the retina either retards or prevents the reapplication of the detached retina. The theory of the choroidal exudation holds true in the pathogenesis of detachment of the retina in those cases in which the detachment is due to nephritic retinitis, exudative chorioiditis and orbital diseases. When the detachment is caused by exudation, the retina may reapply itself if the exudates are reabsorbed. This is what happens in cases of retinitis complicating pregnancy. The theory of the retraction of the vitreous body seems logical when there are either vitreous hemorrhages or loss of the vitreous humor, because, during their reabsorption, retractile and cicatricial adhesions are formed. This theory however loses a great part of its value if one considers the absence of retinal detachment in the aged following removal of a cataract or of the vitreous body, by Zur Nedden's method. The reapplication of the retina to the superior part of the detachment in cases in which a superior detachment becomes an inferior one shows also the lack of truthfulness of the theory of the retraction of the vitreous body. Dr Arruga believes that idiopathic detachment of the retina is due in most cases to a lesion in the retina itself. If the retina is normal and healthy it is not easily detached, even if it is torn. In the production of retinal detachment there are several factors involved, that is, an energetic action of the vitreous body and the choroid and some special condition in the retina itself. Experiments have shown that in order to cause detachment it is necessary to provoke large tears in the retina, a total withdrawal of the vitreous humor or an intense irritation of the choroid, and even in these conditions the detachment may be cured. The numerous retinal changes in the aged, which are invisible in ophthalmologic examinations, as well as certain types of iridocyclitis which cannot be seen by direct examination of the eye but which can be discovered by the slit lamp may be made worse by the operation. Some nutritional disturbances and deficiencies of the liver and kidneys have an unfavorable action on the retina. Hypotension is due to the reabsorption of the vitreous humor by the choroid. It may be modified by psychic or moral disturbances and it favors detachment. Sclerosis of the retina favors detachment also in cases of small retinal tears. The form of the tear depends on the presence of adhesions between the

vitreous body, the retina and the choroid. The greater specific gravity of the subretinal fluid explains the progress of the detachment in a downward direction. It also justifies the position in which the patient is kept after the operation that is, on the side on which the operation was performed.

Dr Giuseppe Ovio of Rome spoke on the history of the treatment of detachment of the retina. When the real pathology of the condition was still unknown, it was considered as a form of amaurosis in the correction of which medical treatment was resorted to. Ware proposed the puncture of the sclerotic coat to evacuate the subretinal fluid. Samelsohn in 1875 advised the application of a bandage causing compression in the eye while the patient was lying in dorsal decubitus. Nowadays, medical treatment is used according to Samelsohn's precepts. Besides that, several other measures such as having the patient in the dark, diaphoresis, the instillation of physostigmine and atropine, electrolysis, massage, the administration of iodine, mercurial and arsenical preparations, tuberculin therapy, a diet with little salt, and subconjunctival or intravitreal injections are used. The subconjunctival injections were recommended by Grosmann in 1883 although they became more widely used through the experiments of Mellinger in 1894. The foregoing measures are all based on logical conceptions. During the last half of a century there have been optimistic and pessimistic tides. Statistics presented by the author show that, under medical treatment, improvement occurs in 22 per cent of the cases and recovery in 22 per cent.

Dr Alfred Vogt of Zurich spoke on surgical treatment of detachment of the retina. Rest is such an important factor in treatment that alone it may accomplish the cure. The aim of surgical treatment of detachment of the retina is to close the tear. Galewski was the first to perform systematic thermocauterization of the retinal tear as a treatment for detachment of the retina. Retinal perforation may be of traumatic origin. The so-called spontaneous perforation of the retina may be favored by trauma in the presence of destructive processes of the retina, such as senile and presenile degeneration, myopic atrophy and cystic degeneration. The destruction of the vitreous humor parallels that of the retina. The spontaneous detachment is caused by either a tearing or a perforation. The hypotonia coexisting with the detachment is the result of the perforation and it disappears when the perforation is closed. To succeed in closing the perforation it is necessary to locate its origin, which may be done by ophthalmoscopic examination. Cauterization by using the apparatus of Gonnin, electrocauterization, the chemical method of Guist, and diathermy according to the technic of Weve are the most important operative methods in use. The most simple method is ignipuncture by cautery and diathermy needle which prevents loss of the vitreous humor. Cauterization with the needle should be exceedingly rapid (from one to three seconds). Otherwise, serious injury may result. The author advised the use of the needle of Weve in cases of small perforations located near the choroid and the use of the galvanocautery in cases of extensive perforations near the ora serrata. Generally, two cauterizations are necessary to cure an extensive tear.

Trachoma and blindness were also discussed during the congress. Dr Wibaut of Amsterdam said that in 1931 an inquiry in which a great number of ophthalmologists from several countries took part was opened to study the initial symptoms of trachoma. It was found that in countries where trachoma is endemic the diagnosis is made long before the time of appearance of complications or scars. The difference of opinion among ophthalmologists rests on the fact that some of them consider certain cases as either benign or early forms of trachoma while others regard them as cases of follicular conjunctivitis. Most ophthalmologists however consider the early noncomplicated forms of trachoma highly important. These early forms are frequently observed in chil-

dren of preschool and school age. The author advised the systematic examination of children in school, at home and in the kindergarten in order to discover early cases of trachoma. These uncomplicated forms, if properly treated, may exist a long time without complications, even in those countries in which the virulent forms of the disease are not uncommon. The detection and treatment of trachomatous children are important in the campaign against trachoma. Instead of being sent away from school, trachomatous children should be treated in those educational centers.

Dr Riccardo Galeazzi of Rome presented statistical studies demonstrating the possibility of producing in the eye a local immunity by means of a polyvalent vaccine made with bacteria isolated from patients having different kinds of ocular infections. The author believes that trachoma is due to the association of bacteria superposed on a constitutional trachomatous substratum which is identified with adenoidism.

Dr P. K. Olitsky of New York reported the results of his experiments related with the transmission of trachoma from man to monkey. If the normal conjunctiva of monkeys is rubbed with secretions from trachomatous patients, or if monkeys receive a subconjunctival injection of trachomatous tissue of human origin characteristic granular conjunctivitis develops, and the disease may be transmitted from monkey to monkey. The speaker started a series of similar transfers with cultures of *Bacterium granulosis* obtained from human trachomatous material. The period of inoculation of the disease, the transmission of the infection from the inoculated eye to the normal one, and the appearance, first, of the initial lesions and, later on of the well developed lesions, as well as the histopathologic changes, are identical in animals in which the infection is transmitted by cultures and in those in which it is transmitted by infected tissues. The characteristic experimental lesions originate around the vessels, thus proving that the genesis of experimental trachoma is similar to that of human trachoma.

By the superposition of secondary infections in monkeys, following the inoculation with *Bacterium granulosis* it is possible to produce ocular lesions with a clinical aspect similar to that observed in florid trachoma in man. By the intracorneal injection of any agent with slight infective capacity, it is possible to produce in the animal a persistent keratitis similar to panus tenuis in trachoma in man. The active etiologic agent of these lesions is *Bacterium granulosis*. The intracorneal injection of these bacteria provokes the development of pseudopanul, which may persist at least for two years without regression of the lesions. The hypothesis that trachoma is a disease caused by an ultramicroscopic virus has not been as yet proved.

Dr Manuel Marquez of Madrid spoke on the necessity of making a rational classification of the causes of blindness and he presented a classification in the form of a chart.

At the closing of the congress, a resolution was passed to be presented to the governments of several countries as a reaction of ophthalmologists against the charlatanism of those who sell eyeglasses or adjust them without being ophthalmologists. The congress moved that persons who sell glasses should do so only when they are prescribed by ophthalmologists; the only persons scientifically prepared to know the needs of their patients.

Loewenstein's Studies on Tuberculosis

Dr Ernst Loewenstein of Vienna recently lectured in the Escuela de Sanidad of Madrid on his studies on the tubercle bacillus. The culture is made in a nutritive medium of the yolk of egg, after the material under investigation has been washed in a 15 per cent solution of sulphuric acid. All bacteria except the tubercle bacillus are killed in the solution. The speaker is able to show the presence of characteristic colonies of tubercle bacilli, even to macroscopic examination in 80 per cent of the cases when the cultures have been made with the blood of tuberculous patients. Dr Loewenstein explained in

detail his method of culture and stated that he has modified his conception on the etiology of tuberculosis. At first he found tubercle bacilli in the blood of patients with several clinical forms of tuberculosis—pulmonary, renal, cutaneous and osseous. The speaker found, later on, tubercle bacilli in the blood of patients with acute articular rheumatism. Up to July 1, 1932 he had made cultures from 1,430 specimens of blood of patients with acute articular rheumatism, 432 of which gave positive results for tubercle bacilli. Kren reported positive results in 100 per cent of the cases of lupus erythematosus when the disease was in evolution. The speaker, in collaboration with Dr. Karl Amersbach of Prague, made an examination of the tonsils and of the blood of several patients with polyarthritis. They detected tubercle bacilli in the tonsils of twelve patients with polyarthritis, in the blood of eight and in the blood and tonsils of two. The presence of tubercle bacilli in the tonsils and in the blood of polyarthritic patients confirmed the work previously reported by the speaker in collaboration with Reitter. Reitter believes that the presence of tuberculous bacillema, increased allergy and increased filtration of the vessels, which may be caused either by an infection or by a trauma, are the necessary factors for the development of polyarthritis. Tubercle bacilli are in the blood of patients with chorea only during the early periods of the disease. The diagnosis of tuberculosis must be made from the fact that tubercle bacilli exist in the blood and not on the basis of characteristic tuberculous lesions in the tissues. The detection of tubercle bacilli in the blood is direct proof for the diagnosis of tuberculosis, while the presence of reactions of the tissues is indirect proof. The reaction of the tissues depends on several factors, such as the quality, quantity and strain of the bacilli, the conditions of immunity, the resistance of the tissues to the infection, and the portal of entry of the infection. The so-called tuberculous structure is only a phase in the cycle of the alterations caused by tubercle bacilli in the tissues. As Aschoff said in the Congress of Internal Medicine in 1921, "tuberculosis may produce both the typical histologic image of tuberculosis and the most varied aspects of inflammation." Loewenstein believes that there are certain forms of tuberculosis without a tuberculous structure, which follow the evolution of an acute or subacute infection, either with or without fever. On this ground, the speaker has tried to isolate tubercle bacilli in several diseases and pathologic conditions such as in dementia praecox. He found tuberculous bacillema in 142 of a group of 359 cases of dementia praecox. Tuberculous bacillema was discovered in four out of six cases of retrobulbar neuritis. According to Loewenstein retrobulbar neuritis, which was believed to be caused by the abuse of alcohol or tobacco is only an initial symptom of multiple sclerosis. The speaker believes that tuberculosis of the intima of the vessels causes first the internal erosion of the vessels followed by ulceration and sometimes by the rupture of the vessel. Tuberculosis of the intima is also responsible for the propagation of the tuberculous bacillema. Loewenstein insisted on the existence of tuberculosis without the presence of a tuberculous nodule. Tuberculosis is, by preference, a vascular disease. Tubercle bacilli attack the endothelium of the vessels. The diagnosis of tuberculosis should not be excluded in necropsies until after a microscopic study and cultures of the organs suspected to be tuberculous have been made. The macroscopic examination of the organs is insufficient to make a correct diagnosis. That tuberculosis is a general and not a local disease is demonstrated by the clinical course of the disease, by its metastases to the various organs, by the characteristic fever chart, by the reaction of the conjunctiva of the tuberculous organism to tuberculin and by the presence of tuberculous bacillema. The detection of tubercle bacilli in the blood is of more value in the diagnosis than the tuberculin reaction and the complement fixation test.

(To be continued)

Marriages

JOHN MALLOY CLAYTON COVINGTON, Roanoke Rapids, N. C., to Miss Madge Westmoreland Balcome of Greenville, S. C., May 27.

WALTER MAUTHE, JR., Whitewater, Wis., to Miss Marie Joan Rolfs of Milwaukee, June 1.

CECIL E. NEWELL, Chattanooga, Tenn., to Miss Gretchen Thelen at Minneapolis, May 31.

RAYMOND H. KING, La Grange, Ga., to Miss Eleanor Haight of Jacksonville, Fla., April 28.

BERTHOLD AARON FREY, Los Angeles, to Miss Gertrude Cohen of Chicago, June 11.

ISADORE L. LEVIN, Lorain, Ohio, to Miss Judith Quasser of Portsmouth, May 28.

HAROLD E. ROE, Los Angeles, to Miss Leona Livingston at Chicago, May 6.

JOHN J. HOPKINS to Miss Iva Bromley, both of Decatur, Ill., May 7.

Deaths

Edward Osgood Otis, Exeter, N. H., Harvard University Medical School, Boston, 1877, emeritus professor of pulmonary diseases and climatology, Tufts College Medical School, Boston, member of the Massachusetts Medical Society and the American College of Physicians, member and past president of the American Climatological and Clinical Association, past president and honorary director of the National Tuberculosis Association, past president of the American Public Health Association and the Massachusetts Tuberculosis League, in 1901 delegate to the Congress on Tuberculosis in London and in 1912 to the International Congress on Tuberculosis in Rome, corresponding member of the International Anti-Tuberculosis Association, major, medical reserve corps, U. S. Army, served during the World War, for many years on the staff of the Boston Dispensary and formerly visiting and consulting physician to the Rutland (Mass.) Sanatorium, author of "Tuberculosis, Its Cause, Cure and Prevention," and "Pulmonary Tuberculosis," aged 84, died May 28.

Waldo Webster Walker, Boston, State University of Iowa College of Homeopathic Medicine, Iowa City, 1913, member of the American Academy of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons, assistant professor of laryngology and rhinology, Boston University School of Medicine, surgeon in the nose and throat department, Massachusetts Memorial Hospitals, aged 48, died, May 15.

John Howard Harter, Seattle, Western Reserve University School of Medicine, Cleveland, 1916, member of the American Academy of Ophthalmology and Otolaryngology and the Pacific Coast Oto-Ophthalmological Society, fellow of the American College of Surgeons, on the staffs of the Columbus and Swedish hospitals, aged 45, died, May 13.

Thomas J. McKinney, Champaign, Ill., Medical College of Indiana, Indianapolis, 1883, Northwestern University Medical School, Chicago, 1898, member of the Illinois State Medical Society, fellow of the American College of Surgeons, on the staff of the Julia F. Burnham Hospital, aged 73, died, May 27, in the Kenilworth (Ill.) Sanatorium.

Waldemar Theodore Browne, New Orleans, Long Island College Hospital, Brooklyn, 1909, member of the Louisiana State Medical Society, veteran of the Spanish-American and World wars, director, bureau of communicable diseases, Louisiana State Board of Health, aged 58, died May 8, in the Charity Hospital, of heart disease.

Thomas Wray Grayson, Pittsburgh, Western Pennsylvania Medical College, Pittsburgh, 1897, member of the American Gastro-Enterological Association and fellow of the American College of Physicians, served during the World War, aged 61, died, May 16, of bulbar paralysis and cerebral hemorrhage.

Walter R. McCray, Charles City, Iowa, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900, past president and secretary of the Floyd County Medical Society, formerly county coroner, aged 58, died, May 15, in the Cedar Valley Hospital, of uremia.

Robert Patton Hoxsey, Beatrice, Neb College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1901, member of the Nebraska State Medical Association, on the staff of the Nebraska Institution for Feeble Minded, aged 63, died March 23 of angina pectoris

James Calhoun Harris, Anderson, S C University of Maryland School of Medicine, Baltimore, 1883, member of the South Carolina Medical Association fellow of the American College of Surgeons, aged 74, on the staff of the Anderson County Hospital, where he died, May 8, of angina pectoris

Louis Bernard Knecht ♂ Mescalero, N M., Washington University School of Medicine, St Louis, 1910, member of the Missouri State Medical Association, served during the World War physician in charge of the Mescalero Indian Hospital, aged 45, died, May 28, of a self inflicted bullet wound

Morton Byron Fishbaugh, Celina Ohio, College of Physicians and Surgeons Baltimore, 1893, member of the Ohio State Medical Association, president of the Mercer County Medical Society, aged 67, died May 30, in a hospital at Lima, following an operation for gallstones

Eugene Cohn ♂ Kankakee, Ill., Barnes Medical College, St. Louis, 1898, Northwestern University Medical School, Chicago, 1906, fellow of the American College of Surgeons, formerly superintendent of the Kankakee State Hospital, aged 58, died, May 30, of heart disease.

Frederick Charles Esselbruegge ♂ St. Louis, Washington University School of Medicine, St. Louis, 1906 served during the World War on the staff of the Christian Hospital, aged 49, died May 22, of pneumonia, following an operation for appendicitis

Kenneth Moncur Lindsay, Buffalo, University of Western Ontario Medical School, London, Ont., Canada 1928, member of the Medical Society of the State of New York, aged 31, died, March 10, in London, Ont., of pneumonia

Elmer Forrest Hayden, Tulsa Okla., University of the South Medical Department, Sewanee, Tenn, 1899, member of the Associated Anesthetists of the United States and Canada, aged 56 died May 21, of heart disease.

Minor Revere Adams, Statesville, N C University of Maryland School of Medicine, Baltimore, 1878 member of the Medical Society of the State of North Carolina, aged 78, died suddenly, May 27, of heart disease

George B Burrus, Woodland Mills, Tenn University of Nashville Medical Department, 1886 Vanderbilt University School of Medicine Nashville 1886 aged 75, died, April 28, in a hospital at Jackson.

William Robert Blackburn, Virginia, Ill., Barnes Medical College St. Louis, 1898 member of the Illinois State Medical Society aged 66 died, May 3, of pulmonary thrombosis and chronic myocarditis

James Harney Fountain ♂ Chapin Ill Rush Medical College, Chicago, 1881 aged 74 died May 14 in the Passavant Hospital, Jacksonville of morphine poisoning, presumably self administered

Forbes Hamilton Broughton, Wolcottville, Ind Indiana Medical College Indianapolis 1874, Civil War veteran, aged 84 died May 26 of chronic myocarditis, hypertension and arteriosclerosis

Bruce McVean Mackall, Washington, D C Georgetown University School of Medicine Washington, D C 1903, served during the World War aged 51, died May 1, of cerebral hemorrhage.

William L Ruggles ♂ Oak Park Ill Chicago Homeopathic Medical College 1891 on the staff of the West Suburban Hospital aged 68 died suddenly, April 29, of heart disease.

Melville Silverberg, San Francisco Johns Hopkins University School of Medicine Baltimore 1902, aged 56, died April 24 of hypertension myocarditis and coronary thrombosis

Joseph Arthur Kuykendall, San Francisco California Medical College, San Francisco 1896 aged 57 died April 20, in the Franklin Hospital of chronic myocarditis and nephritis

Harry M Smith ♂ Las Vegas N M Northwestern University Medical School Chicago 1891 on the staff of St. Anthony's Sanitarium and Hospital aged 63 died April 11

Thomas Mason Evans, Los Angeles Barnes Medical College, St Louis 1905 aged 51 died April 12 in the Olive View (Calif) Sanatorium of chronic pulmonary tuberculosis

Eleanor Clary Stocks, Chicago Johns Hopkins University School of Medicine Baltimore, 1920 aged 40 died May 27, in the Wesley Memorial Hospital, of bacterial endocarditis

Harry E Mayor, Troy Grove, Ill., Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1900, aged 57 died, May 22, as the result of a cerebral hemorrhage

Horatio N Boshell ♂ Melvin, Ill., Rush Medical College, Chicago, 1895, aged 61, died, May 27, in St. Mary's Hospital, Kankakee, of injuries received in an automobile accident

Thomas Byron King ♂ Gainesville, Fla., Atlanta School of Medicine, 1911, on the staff of the Alachua County Hospital, aged 46, died suddenly, May 7, of heart disease

James J Rhodes, Cummings Kan., University Medical College of Kansas City, 1900, member of the Kansas Medical Society, aged 54, died May 20, of chronic nephritis

William N Edenfield, Vienna, Ga., University of Georgia Medical Department, Augusta 1892, member of the Medical Association of Georgia, aged 68, died, April 17

Maury B Linkous, Blacksburg, Va., University College of Medicine, Richmond, 1899 member of the Medical Society of Virginia, aged 59, died suddenly, April 29

Victor Theodore De War ♂ Grand Junction, Colo., Northwestern University Medical School, Chicago, 1928, aged 31, was killed, May 26, in an airplane accident.

Alfred Bradley, Barthell, Ky., University of Louisville (Ky) School of Medicine, 1909, member of the Kentucky State Medical Association, aged 57, died, April 14

Frank Sperber ♂ New York University and Bellevue Hospital Medical College, New York 1921, aged 35, was killed, May 18 in an automobile accident.

Joseph W Lowry Ironton, Ohio University of Louisville (Ky) School of Medicine 1893 aged 66, was found dead in bed, May 24, of cerebral hemorrhage.

Roswell Elmore Flack ♂ Memphis Tenn Johns Hopkins University School of Medicine, Baltimore, 1913, aged 55, died, May 23, of cerebral hemorrhage

Edward Joseph Sullivan, Boston, Tufts College Medical School, Boston, 1931, aged 27 intern, Boston City Hospital, where he died, May 17, of pneumonia

Carl Frederick Haish, Santa Ana, Calif., Kansas Medical College, Medical Department of Washburn College, Topeka, 1897, aged 67, died, March 26

Leander F Cain, Caldwell Ohio, Kentucky School of Medicine, Louisville, 1877, formerly member of the state legislature, aged 76, died, April 27

Steve Harmon Anderson, Kilm Miss Mississippi Medical College, Meridian, 1907 aged 57, died, May 5, of actinomycosis of the scalp and skull

W D Frederick, Sidney, Ohio Physio-Medical College of Indiana, Indianapolis 1884 aged 72, died suddenly, May 10, of cerebral hemorrhage

John F Barthell, Howard S D., State University of Iowa College of Medicine Iowa City, 1891, aged 64, died, April 30, of angina pectoris

Henry Driessel, Kewaskum, Wis Louisville (Ky) Medical College, 1898 for many years health officer of Kewaskum, aged 80 died April 25

Waldo Unruh Kurtz, Wanamassa, N J Trinity Medical College Toronto, Ont Canada, 1896, aged 65 died, May 14, of cerebral hemorrhage

Ross Allen Harris, Los Angeles Rush Medical College, Chicago, 1899 aged 68 died April 17, of coccidioidal granuloma with meningitis

Fouche Warren Samuell, Louisville, Ky., Kentucky School of Medicine Louisville, 1886, aged 66 died suddenly May 13, of heart disease

James Allen Lynch, Pendleton, Texas Hospital College of Medicine, Louisville, Ky., 1877, aged 82 died May 6, of myocarditis

George W Haverstick, University City, Mo Beaumont Hospital Medical College, St. Louis 1895 aged 65, died April 30

Lorne Drum Ottawa Ont Canada McGill University Faculty of Medicine, Montreal, Que., 1896 aged 62 died April 17

George Hugh McCain, Whitehaven Tenn Memphis Hospital Medical College 1890, aged 66, died, May 11, of heart disease

George P Hitchcock, Los Angeles, Hahnemann Medical College and Hospital Chicago 1904 aged 75 died April 25

Anna C Shipley, Seaford Del Woman's Medical College of Baltimore 1902 aged 65, died May 8, of heart disease

Luther Lafayette Sapp, Reidsville N C Jefferson Medical College of Philadelphia 1889 died April 5

Correspondence

"TRAUMATIC ULCER OF THE DUODENUM AND STOMACH"

To the Editor—In THE JOURNAL, May 27, Drs Crohn and Gerendasy report a case and discuss the subject of traumatic ulcer of the duodenum and stomach. The conclusion that "the evidence seems convincing that the trauma caused the ulcer" might be misleading. The reference to "students of gastroenterology refusing to accept the concept of traumatic gastric ulcer" calls for elucidation as to just what this concept is.

The four postulates of Linger and Molineus satisfactorily exclude cases of pseudo-ulcer but fail to explain why gastro-duodenal trauma should be followed by the development of ulcer in certain cases and not in others.

The evidence in the reported case is certainly convincing, that the trauma caused the injury to the duodenal mucous membrane. Of this sequence there can be no reasonable doubt.

Because the intestinal mucosa, like the skin, has an inherent tendency toward repair, something more than the injury is probably necessary to cause chronic ulcer, such as the presence (or absence) of a something in the gastric content or in the body fluids or cells that interferes with spontaneous healing of the damaged duodenal mucous membrane.

Under the heading of pathology it is stated that "the symptoms point to the formation of a true peptic ulceration occupying the seat of the trauma and caused, presumably, by the peptic digestion of the lacerated and blood-suffused mucosal tissue." It is such a condition of hypergastric function or hyporesistance to gastric juice, called "an ulcer constitution and chemism" that may convert a simple contusion, laceration or abnormality of the gastro-intestinal wall into a true chronic ulcer.

It should be emphasized that the trauma may be severe and grossly evident or so slight as to be unappreciated and that it may be either physical or psychic.

Recognition of the fact that the trauma may be a preliminary factor and not a final cause is not merely academic but may be of medicolegal importance and of therapeutic value.

Treatment should aim at prevention or repair of perforation, hemorrhage or obstruction at the correction of this 'ulcer constitution' to promote healing of the gastric or duodenal traumatism, and at the avoidance of additional trauma.

GREGORY CONNELL, M D, Oshkosh, Wis

"COMMERCIAL ASPECTS OF BACTERIOPHAGE THERAPY"

To the Editor—I would like to congratulate THE JOURNAL for blasting the commercial aspects of bacteriophage therapy in the issue of May 20. I only wish that the rank and file of the profession would wait for the report of the Council on Pharmacy and Chemistry before swallowing hook, line and all of the bacteriophage panacea.

A valuable article appeared in *Northwest Medicine* (32:106 [March] 1933) on "Mobilization of the Reticulo-Endothelial Cells as Aid to Cure," by Dr S H Tashjian of Seattle. He uses nutrient broth, which seems to do everything claimed by different "phagists."

In the clinic with which I am associated we have had similar results with nutrient broth injections for carbuncles, chronic indolent ulcers, varicose ulcers, and a wide variety of infections. Similar results from other clinics and hospitals are daily reported. I think this is a forward step in modern therapeutics with a scientific basis.

O F LAMSON, M D, Seattle.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

ANOREXIA IN ADOLESCENTS

To the Editor—A boy aged 17 whose family history was negative with the exception that the mother had stomach trouble during childhood had children's diseases of no unusual character and what might have been a mild muscular rheumatism tonsillectomy was performed two years ago. Since that time he has had no sensation of hunger at all. He complains of some distress in the epigastrium after two days without food but no hunger. He has vomited once. An urticarial rash has appeared on several occasions. He has lost some weight. His weight is 138 pounds (62.6 Kg) about normal. His general appearance is good. Nervousness was apparent during the examination. His mental make up is better than usual. The blood pressure at the first examination was 152 systolic 85 diastolic. At the second examination some days later 120 systolic, 75 diastolic. The urine was highly acid but otherwise normal. The diet is of insufficient caloric content. The chief complaint aside from lack of appetite is of fatigue on slight exertion and tremor of the hands. Treatment has consisted of the usual bitter tonics hydrochloric acid iron and bromides. Administration of sugar cleared up the tremor and much of the feeling of fatigue. The sense of taste seems to be normal. Otherwise there has been no improvement except a slight gain in weight. Please omit name. M D Michigan.

ANSWER—This unusual anorexia in an adolescent boy may have an organic basis. Anorexia, fatigue and tremor are the only symptoms and signs mentioned. The blood pressure at first examination was, no doubt, elevated by nervousness, as the recorded blood pressure determination would be within normal limits for this patient.

The anorexia, fatigue and tremor might all be caused by a mild degree of hyperthyroidism. Enlargement of the thyroid gland at this age is most commonly a simple colloid goiter. However, eye signs, vasomotor instability and tachycardia combined with determination of the basal metabolic rate, would aid in the establishment of such a diagnosis.

An incipient tuberculosis at puberty might evidence itself by the signs and symptoms mentioned. Careful physical examination, combined with laboratory sputum and roentgen examinations, would establish the diagnosis of such a condition. A negative tuberculin reaction would be valuable in ruling it out.

Chronic peptic ulcer, of which hunger pain and anorexia are symptoms, is uncommon but not unknown at this age. Ulcer may be associated with allergic manifestations, which could account for the urticarial rash noted on several occasions. An Ewald meal, stool and roentgen examination would aid in the verification of such a diagnosis. If all organic etiologic explanations of the patient's signs and symptoms are found negative a constitutional or functional disorder must exist. Children with an asthenic constitution are of poor nutrition, with a weak flabby musculature. The appetite is frequently impaired, and constipation is the rule. Gastric dilatation and ptosis of the abdominal viscera are frequent. Gastric acidity is often diminished or absent. Atony, enteroptosis, neurasthenia and dyspepsia have been considered the most important criteria for the diagnosis of a constitutionally asthenic child.

Asthenia is not uncommon during adolescent life and tends to recede with advancing years. The treatment in such a condition consists in exercise to strengthen the body musculature. Abdominal support for ptosis is of value, and a coarse diet, with plenty of fruits, vegetables, coarse cereals, butter, cream, eggs, milk and sugar will aid constipation and, by adding weight, will help to relieve ptosis and digestive disturbances.

SODIUM AMYTAL AND TRIBROMETHANOL AS ANALGESIC IN LABOR

To the Editor—Can sodium amytal and Avertin (tribrom-ethanol) be combined as an analgesic in obstetric practice? What if anything is wrong with the following procedure if the dose and administration to the patient are proper? In the primary stage of labor with active regular contractions $\frac{1}{4}$ grain (11 mg) of morphine sulphate and $\frac{1}{160}$ grain (0.4 mg) of scopolamine to be followed in two hours by 6 grains (0.4 Gm) of sodium amytal provided this holds the patient fairly comfortable at the beginning of the second stage of labor the correct weight dosage of tribrom-ethanol supplemented with ether if necessary in delivery and perineal repair. Can sodium amytal be carried further than the 6 grain dose and can the scopolamine be repeated without any bad effects? Please omit name. M D Arizona

ANSWER—Sodium amytal has been used extensively in obstetrics during the last few years but opinion concerning its merits is divided. Some praise it unqualifiedly whereas others are dissatisfied with it. The drug has three major

disadvantages First, administration requires some technical skill, hence only a physician should administer it and watch the patient (not a nurse) Second, it frequently produces excessive and annoying restlessness, and this requires an increased personnel in attendance Third the drug makes necessary an increased number of instrumental deliveries Some obstetricians have reported a rather large incidence of narcotized or apneic babies Sodium amytal does however produce satisfactory analgesia, amnesia and relaxation of the soft parts

Tribrom ethanol has likewise been given an extensive trial by some obstetricians, but this drug has a narrow margin of safety Therefore it also must be carefully controlled by a physician and not by a nurse DeLee believes that pregnant women are more susceptible to its deleterious effects than nonpregnant women The drug is pleasant to take and when combined with an inhalation anesthetic is useful in many cases

Since either sodium amytal or tribrom-ethanol when used alone may occasionally produce harm if great care is not used, it is unwise to use a combination of them in the same patient Certainly if morphine and scopolamine are to be used as analgesias and ether as an anesthetic either sodium amytal or tribrom ethanol alone will surely suffice and will be far safer than the two combined It is not advisable to give more than 0.4 Gm of sodium amytal unless labor is much prolonged when an additional 0.2 Gm may be given A second dose of scopolamine may likewise be administered under the same conditions but it is best not to give more than a total of 0.6 mg ($\frac{1}{400}$ grain) throughout labor

USE OF MILD SILVER PROTEIN IN NOSE—TREATMENT OF LARYNGITIS IN CHILDREN—ANTI SEPTIC TROCHES

To the Editor—1 Many children struggle on nasal instillations of medication Do you feel that the instillation of mild silver protein in nasopharyngitis is of more value than the effect of struggling? 2 Is there any objection in using morphine or atropine in treating acute attacks of spasmodic croup (nondiphtheritic) in preference to emetics or inhalations? Kindly suggest the dosage for a child 5 years old. 3 What antiseptic troches if any can you suggest for prevention of contagious disease after contact? Kindly omit name. M D New York.

ANSWER—1 Nasal instillation of mild silver protein is objectionable not only because it is probably of little value and causes struggling but also because it discolors the nares, handkerchief and bedding

2 Morphine should not be used in the bronchitis of children because of the danger of retention of secretion hence it should not be employed in laryngitis because of the likelihood of its being complicated with bronchitis At the most minimal doses should be given The dose of morphine sulphate for a child of 5 may be placed at 0.003 Gm but probably not more than 1 mg every two hours for three doses, if required would be justifiable in laryngitis Atropine sulphate might be associated with the morphine in one-tenth or one twentieth the dose of the latter Codeine phosphate in doses up to 0.005 Gm might be preferable Spasmodic croup is composed of two elements inflammation of the laryngeal mucous membrane and spasm which is a purely nervous reflex manifestation Inhalations and nauseant expectorants (such as ipecac) have a favorable effect on the inflamed mucosa and should not be omitted The nervous element responds in milder cases to sodium bromide (0.10 Gm for each year) with antipyrine (0.05 Gm for each year) repeated every two hours In severe cases chloral hydrate which might have to be given by rectum in dosage of from 25 to 50 cc of a 1 per cent solution in starch water is useful These sedatives because less specifically antitussic are safer than the opiates in this condition

3 There are no such troches There is nothing powerful enough to disinfect the mouth that could be used in this form

MALARIA IN TEXAS

To the Editor—Is malaria prevalent enough in Texas to warrant taking prophylactic doses of quinine? My patient had the disease while working in that state last year and has come to me for advice as he is to return there in the near future Please omit name.

M D Connecticut.

ANSWER—The advisability of taking prophylactic quinine in this case involves both the severity of malaria in Texas and the general question of the effectiveness of such prophylaxis Compared to most tropical countries the eastern half of Texas where most of the malaria occurs presents only a moderate malaria problem Furthermore although there is still considerable difference of opinion as to the effectiveness of prophylactic quinine, there is a mass of evidence that in the doses usually employed it will not prevent infection although it may hold down the acute clinical symptoms of the initial attack and allow the body to acquire a partial immunity to the infection while still harboring the organism In view of these considerations, it is recommended that the patient be not given so-called prophylactic quinine but that he be advised at the first suggestion of an attack of malaria to consult a physician for diagnosis and early treatment

USE OF DRYCO AS NONSPECIFIC PROTEIN IN PLACE OF MILK NOT RECOMMENDED

To the Editor—I have been using milk injections more or less with impunity for nonspecific protein therapy and recently had the bright idea of making a solution from Dryco which appeared to me to be ideal in that it was a low fat containing natural milk product Following the first intramuscular injection in a case of chronic gonorrhea the patient experienced a terrific reaction which I could not associate with milk from my previous experiences As an afterthought I looked on the can and found a note which showed that all drug store Dryco is irradiated Naturally I attributed the reaction to this activation Could you give me any information on this subject? Are there any reports or references to any literature on the effect of parenteral administration of irradiated biologicals? M D California.

ANSWER—In the absence of specific knowledge or experience, it is believed that the observations of the correspondent on injected irradiated Dryco would be entirely logical Irradiation with ultraviolet rays is known to affect proteins and, in certain cases, irradiated Dryco or, in fact, other irradiated protein material might give the reaction noted

Though no references in the medical literature shed light on the question, there is ample technical evidence to the fact that the nature of protein material is altered by irradiation In the present instance, however, this particular reaction should not be accepted as a specimen case The question of reaction when protein is injected into the blood stream always involves susceptibility of the individual Whether the case in hand is typical of milk protein or whether the idiosyncrasies of the patient are the dominant factor is something that could be determined only by further investigation

In promiscuously injecting unknown milks, one would seem to be taking a long chance, and many things might happen which could be accounted for other than by irradiation to which Dryco has been subjected As one authority sees the matter, injection of promiscuous milks because they happen to be milk is not considered to be ideal practice

INSULIN REACTION IN DIABETES

To the Editor—A woman aged 44 has been taking insulin for several years and for some time now has presented this problem The insulin dosage is 30-25 U units for meals The urine clears of sugar after the evening meal but she is awakened about 1 or 3 a. m. with marked nervousness sweating and hunger Sometimes she takes a little orange juice and sometimes she takes nothing but the first specimen she passes in the morning before breakfast always shows heavy sugar Omitting the evening dose of insulin eliminates this reaction At the time of the reaction the urine is sugar free I have used low carbohydrate diets and am now having her on a diet of 150 Gm of carbohydrate 60 Gm. of protein and 110 Gm of fat I would appreciate any advice you might give me that I might eliminate the insulin reaction during the night and at the same time clear up the morning glycosuria. Please omit name.

M D Iowa.

ANSWER—A case such as described always presents a difficult problem Physical activity seems to have a great influence on the carbohydrate balance in such patients and it is sometimes impossible to avoid early morning glycosuria without disturbing the normal daily routine From the point of view of the patient's welfare, it is doubtful whether such glycosuria is harmful, provided the diabetes is well controlled through the rest of the twenty-four hours However, if it is considered worth while disturbing the present control of the case, the following rearrangement of the dosage of insulin might be tried breakfast, 35 lunch 0, dinner 15, bedtime (say 11 to 12) 10 units This should allow the patient to go to bed with a higher blood sugar level, so that no reaction ought to be expected at 1 or 2 in the morning The bedtime dose of insulin however should reach the height of its effect at about the time the patient's blood sugar naturally rises and may thus eliminate the early morning glycosuria It may be safer, in this case, to try the breakfast and dinner doses only for a day or two, before starting the bedtime dose, in order to become quite certain that the patient is going to bed with a moderately high blood sugar level The size of the suggested doses are, of course, only guesses and should be readjusted according to the reaction of the patient The higher carbohydrate diet now being received should favorably influence the treatment.

TOXICITY OF ACRIFLAVINE USED INTRAVENOUSLY

To the Editor—The following statement is taken from a booklet compiled by a leading physician Gonorrhoea—In the Male Inject intravenously 5 cc. of a 2% solution of neutral acriflavine (Abbott) A daily injection is given for the first week and 3 times weekly thereafter for from 12 to 36 injections the minimum and maximum respectively that I have found necessary for complete cure No other treatment is necessary though there is no objection to combining with local treatment if so desired Please let me know what THE JOURNAL thinks of it. Would the procedure be safe? Please omit name and address

M D Georgia

ANSWER—P J Crittenden (*J Pharmacol & Exper Therap* 44 423 [April] 1932) states that certain preparations of acriflavine are definitely toxic, causing changes in the heart rate circulation and respiration and nausea and vomiting in intravenous doses of from 2 to 5 mg per kilogram A neutral preparation of acriflavine can be prepared which in doses of from 1 to 2 mg per kilogram causes slight or no changes in the heart rate respiration and blood pressure. Even the least toxic preparation of acriflavine in small doses stimulates and in larger doses depresses the peripheral vagal mechanism of the heart

Heathcote and Urquhart (*J Pharmacol & Exper Therap* 38 145 [Feb] 1930) were prompted to study the pharmacologic and toxicologic actions of acriflavine because of two deaths after the intravenous use of the drug, one death being due to jaundice and the other to acute yellow atrophy Experiments on dogs and rabbits showed that a dose of 30 mg of acriflavine per kilogram intravenously caused death in one hour, with symptoms first of respiratory failure with asphyxia and then the heart ceased to beat In fifteen dogs the pathologic examination revealed marked changes in the kidneys and the liver

ADDICTION TO ACETANILID

To the Editor—I have had a good deal of experience taking patients off of narcotics and have found that when the drug is stopped all at once instead of a tapering off the patients have delusions and hallucinations A few months ago I had occasion to attend a man who had been in the habit of taking about 60 grains (4 Gm) of acetanilid a day His lips were bluish and his skin was chalklike I stopped the drug immediately and for about ten days the patient was a raving maniac I have had experience with one other person who used acetanilid by sniffing The effect produced on the patient in this instance was the same as found in a cocaine fiend 1 Will acetanilid taken by mouth in quantities as large as 60 grains a day cause the patient to become addicted to the use of the drug as a dope fiend would to any other narcotic? 2 Will the reaction be the same as far as mental disturbances are concerned as that of a morphine or cocaine addict if the drug is stopped all at once 3 Will the mental condition produced by the taking of 60 grains of acetanilid a day be on a par with that of any other dope fiend while under the influence of the drug? Please omit name

M D South Carolina

ANSWER—1 There is no doubt that acetanilid addiction can and does occur

2 While the reaction to sudden deprivation of the habituated drug may be similar to that of sudden withdrawal of morphine or cocaine such is usually not the case.

3 No The euphoria-producing tendencies of morphine and cocaine are notoriously greater

URTICARIA PIGMENTOSA

To the Editor—I should appreciate your giving me some information with regard to treating and diagnosing a case I have The patient a girl aged 3 has had an urticaria since she was 3 weeks old It resembles the picture of urticaria pigmentosa in the Atlas of Diseases of the Skin put out by P Blakiston's Son & Co At times it seems to be made worse by milk She has a dry skin and is very nervous I treated the father for syphilis about three years before the child was born He had a negative Wassermann reaction before he married and it has been negative ever since The child's blood and the mother's have been negative each time I have had it examined Please omit name

M D Florida

ANSWER—Urticaria pigmentosa is not urticaria and has no relation to syphilis Its etiology is unknown though many authorities hold that it is a form of nevus Milk should not be blamed unless it can be shown definitely to cause increased itching The dry skin should be protected from the drying effect of soap and hot water, after the bath, ointment of rose water should be applied Oatmeal water may be used for the bath If this does not prevent itching two parts each of Pusey's calamine liniment calamine powder and zinc oxide in sixteen parts each of solution of calcium hydroxide and olive oil may be used frequently, an antipruritic such as coal tar solution, from 5 to 10 per cent, being added if necessary In certain cases the brown spots have gradually disappeared after some years in others they have persisted indefinitely The only treatment that may affect them is radiotherapy, suberythema

doses of x-rays or radium Larger doses are not justified This should be tried preferably on one spot first The disease is harmless aside from the cosmetic defect.

The child in question should be watched for signs of syphilis until after puberty but no treatment for syphilis should be given until it is shown to be present

DETERMINING FUNCTIONAL POWER OF TESTIS

To the Editor—A man aged 44 was operated on for hydrocele In the operative procedure the surgeon cut through the skin muscles and tunica and sliced deeply into the testicle which at that time was perfectly normal When the testicle was incised the incision extended deeply in fact almost half the tunics poured out of the incision and much of the tissue was wiped away with sponges It was one of those accidents that do occur The testicle proper was sutured and a typical bottle operation was performed for the hydrocele After the operation which took place July 5 1918 the hydrocele promptly recurred and is now quite large and has persisted from the date of operation to the present At a later date in 1919 the patient married and became the father of two children one born in 1920, the other in 1922 At present examination the traumatized testicle is approximately three or four times the size of the normal testicle The patient claims that he has lost the procreative power of the enlarged highly sensitive, exquisitely tender testicle which opinion is concurred in by several examining physicians and surgeons There is no evidence of a tendency toward malignancy What I want to know is What means or what method of procedure or examination can a physician undertake to determine whether or not procreative power has been lost? That is the question that must be determined I know of no way of determining the absolute facts except by the presumptive evidence of loss of function as manifested by hyper trophy hyperplasia the engorgement loss of tubules and scar tissue and presence of recurrent hydrocele extending up and involving the cord and the external ring of the inguinal canal I will thank you for an opinion on this case and also citation of authorities Please omit name

M D Texas

ANSWER—There are two ways of determining more or less accurately the procreative function of a testicle. One is to catheterize the ejaculatory duct on the side through the posterior urethroscope and examine the fluid thus obtained for spermatozoa. The other method is to stick a rather large aspirating needle attached to a syringe into the testicle and epididymis and aspirate these parts and examine the aspirated fluid thus obtained for spermatozoa The latter procedure is simple but gives no information as to the permeability of the various tubes that convey the spermatozoa from the testicle to the urethra

INJECTION OF VAS FOR VESICULITIS

To the Editor—What is the status of injections into the vas with dis infectants for chronic vesiculitis in old cases of gonorrhea? If advisable what chemicals are best suited?

G W MONTGOMERY M D Caldwell Idaho

ANSWER—The injection into the vas deferens of various germicidal drugs for the treatment of chronic vesiculitis has had extensive trial and has proved of but questionable benefit The necessity of incising the duct in order to inject the germicidal solution adds to a somewhat minor surgical procedure the possibility of postoperative stricture, which is increased if the fluid injected is at all irritating Moreover, the necessity of making a skin incision in order to reach the duct tends to make a repetition of the procedure unlikely and as a single injection of any medication is seldom curative, the method has been generally abandoned by the majority of urologists or only occasionally employed in the more refractory cases usually with disappointing results Mild silver protein preparations are the drugs most frequently used

DOSAGE OF IRON AND AMMONIUM CITRATE

To the Editor—Dr V C Rowland in his article Anemia of Pregnancy (*THE JOURNAL* February 25 p 539) recommends the use of massive doses of iron—from 90 to 120 grains (6 to 8 Gm) daily—in treating the hypochromic type of anemia He then suggests a 50 per cent solution of iron and ammonium citrate in drachm doses The quantity of iron in a drachm dose of a 50 per cent solution of iron and ammonium citrate is about 5 grains (0.3 Gm) I am wondering whether or not the 'massive doses' refer to the iron salt recommended rather than to the iron itself The Epitome of the U S P states that iron and ammonium citrate contains about 17 per cent of iron Please omit name

M D Long Island N Y

ANSWER—Dr Rowland writes 'The dose of 90 to 120 grains refers to the salt, iron and ammonium citrate In speaking of massive doses of iron, the term iron' is used in a general sense without reference to the particular form or salt used This dosage is massive in comparison with the commonly used amounts of iron previous to the newer methods in the treatment of anemia'

Book Notices

Surgical Pathology of the Diseases of Bones By Arthur E Hertzler MD Surgeon to the Agnes Hertzler Memorial Hospital Halstead Kansas Hertzler's Monographs on Surgical Pathology Cloth Price \$5 Pp 272 with 211 Illustrations Philadelphia J B Lippincott Company 1931

The author gives a clear exposition of all the chief diseases and tumors of bone. The acute inflammatory diseases of bone are divided into those resulting from infection from without and those of the blood borne type. A chapter is added on osteomyelitis in special regions. The clinical features and the gross and microscopic pathology are excellently handled. As in the rest of the book, treatment is not emphasized and the author confines himself strictly to the pathologic features of the disease which he feels will be of benefit to the clinical surgeon. The chapters devoted to chronic inflammation of bone and to specific infection are perhaps too brief. Paget's disease and von Recklinghausen's osteitis fibrosa cystica are included in these chapters with questionable justification. The more common conditions of chronic osteomyelitis Brodie's abscess Garre's sclerosing osteitis tuberculosis and syphilis are well described. A brief review is given of bone diseases of unknown origin, including those dependent on metabolic disturbance about which definite etiologic factors are known, such as rickets and scurvy.

Part II is devoted to tumors of bone. The chapter on osteomas includes hyperostoses ossifying hematoma and exostoses in which the distinction between osteochondroma and osteomas forming in membranous bones are not adequately drawn. This does not detract from the excellence of the pictures chosen to illustrate the various types. In the chapter on chondromas, the author is on surer ground. This is true also of the chapters on myositis ossificans and the chapter devoted to both giant cell tumor and bone cysts. By far the best chapters on bone tumors are those devoted to osteogenic sarcoma. Here the cases and illustrations are well chosen and unusually complete. This is true also of the discussion of Ewing's sarcoma. Multiple myeloma is briefly considered, as is metastatic carcinoma.

The entire book is compact, is easily read and forms an excellent introduction to the subject for the student and the busy surgeon. As a reference book many of the entities discussed are too briefly presented and some listed in the author's own classification, such as chloroma and lipoma, are entirely omitted.

Diseases of the Eye By Hofrat Ernst Fuchs Authorized translation by E A L Brown MD Professor of Ophthalmology University of Chicago. The fifteenth German edition of the 'Lehrbuch der Augenheilkunde' as revised by Maximilian Salzmann Professor of Ophthalmology University of Graz Austria. Tenth English edition. Cloth Price \$7 Pp 641 with 206 Illustrations Philadelphia Montreal & London J B Lippincott Company 1933

The appearance of a new edition of Fuchs has been awaited eagerly by American ophthalmologists. The last English edition was published in 1924. Since that time both Professor Fuchs and his veteran translator, Alexander Duane, have died, but one feels that the demand for this great textbook will continue and will justify the publishers in undertaking this new translation. The choice of Dr Brown long a disciple of Professor Fuchs, translator of Salzmann's Anatomy of the Eye and an authority on the teaching of ophthalmology, to undertake this work was a fortunate one. The idea of publishers and translator was to produce a suitable and not too expensive textbook for American undergraduates. They have therefore reduced the size of the present edition by nearly 400 pages. The chapter on refraction, written by Duane has been omitted in accordance with the translator's belief that refraction should not be taught to American undergraduates. For the same reason the chapter on ophthalmic operations has been omitted.

The chapters on anatomy, physiology, pathology and therapeutics have been omitted as special sections, but much of their material especially that on anatomy, has been redistributed at the heads of various chapters. Thus eight pages are devoted to the anatomy of the cornea fourteen to that of the uveal tract and five to that of the retina and optic nerve in the corresponding chapters an arrangement with obvious advantages. In this arrangement and in all other respects the author has closely followed the fifteenth German edition, as revised by Professor Salzmann. An important addition to this edition over earlier ones is the colored fundus pictures. Forty-one of these drawn by Salzmann and well reproduced, illustrate most of the common and some of the less common ophthalmoscopic conditions. This replaces the twenty-two fundus plates of previous editions. A valuable chapter on the central visual pathways has been added apparently Professor Salzmann's contribution. Duane's well known chapter on motor anomalies which was a feature of later English editions has been replaced by one half as long but excellent in its clearness and choice of the most important matter.

It is hardly necessary to emphasize the qualities that have made this textbook a classic in the teaching of ophthalmology all over the world. Fuchs was essentially a great clinician and his valuable discussions of pathology are not allowed to crowd out his clear and vivid description of the clinical observations necessary for diagnosis descriptions that have never been excelled. The translation is more literal than that of Duane occasional instances of quite Germanic structure being carried over into the English text. It is apparently a completely new translation and on the whole is clear and readable.

One might criticize the absence of any translator's notes which would bring certain subjects down to date. Thus it is strange to see the old description of rheumatic iritis given without any mention of focal infection by one who knows his focal infections as Dr. Brown does while in the Duane edition so-called rheumatic iritis and gonococcal iritis were grouped as focal iritis with proper reference to the importance of various common foci. Another classic concept that seems to require a note of modification is the belief of Fuchs that closure of the central retinal artery is nearly always due to an embolus. The work of Harms and Scheerer seems to leave no room for doubt that many if not most of such cases are due to endarteritis and other causes. One might also object to the statement of Fuchs that therapy is as good as powerless against sympathetic ophthalmia, once it has broken out. On the whole however one need hardly quarrel with an authority who was right as often as was Professor Fuchs. Dr. Brown in following the word of the master as something almost sacred has rendered English-speaking ophthalmologists a signal service.

Text Book of Ophthalmology. By W. Stewart Duke Elder, M.A., D.Sc., M.D. Surgeon Royal London Ophthalmic (Moorfields) Hospital. Vol. 1. The Development, Form and Function of the Visual Apparatus. Cloth. Price \$15. Pp. 1124 with 1029 illustrations. St. Louis: C. V. Mosby Company, 1933.

In the past, textbooks in ophthalmology have been written to appeal to both the undergraduate student and the graduate. This volume is a textbook which offers at the end of each subdivision an adequate and thoroughly up-to-date bibliography sufficiently broad to enable one seeking further literary references to obtain the necessary clues. The first volume is entirely devoted to the fundamental sciences on which a thorough understanding of ophthalmology rests. It contains eight sections on the phylogeny of the visual apparatus, the anatomy and comparative anatomy of the visual apparatus, the ontogenic development of the visual apparatus, the physiology and biochemistry of the eye, optics, the physicochemistry of vision and the physiology of vision including visual sensations.

Owing to the size of the volume it is obviously impossible to discuss it in detail. The various sections are well written, give evidence of careful thought and judgment, present the modern proved concepts of the various subjects and cover ophthalmologic fundamentals in a way that is not even approached in any other single volume. For example, until Adler's book on physiology appeared within the past few weeks there was not a single volume anywhere that dealt with ophthalmic physiology in toto, but this textbook touches on all phases of the subject and gives the reader an insight into the physiologic work that to the average ophthalmologist is unknown territory.

This textbook is one of the best that has ever appeared in English. If the succeeding volume or volumes, as the case may be, maintain the high standard set by the first, English speaking ophthalmologists will not have to make such frequent reference to Teutonic literature as has been necessary in the past.

Operative Surgery Covering the Operative Technique Involved in the Operations of General and Special Surgery. By Warren Stone Blackham, M.D., and Phyllis M. F.A.C.S., Junior Surgeon to Touro Hospital, New Orleans, and Calvin Mason Smyth, Jr., B.S., M.D., F.A.C.S., Assistant Professor of Surgery, Graduate School of Medicine, University of Pennsylvania. Volume VII. Cloth. Price \$10. Pp. 849 with 765 illustrations. Philadelphia & London: W. B. Saunders Company, 1933.

Eight years ago the first six volumes of this work were published. The present volume is an effort to bring the work up to date by adding those operative procedures which have in the last few years become established. The book does not describe every operation that has recently been disclosed but includes only the more important ones. Since anesthesia has developed rapidly within the last few years the opening chapters are on that subject giving special attention to paravertebral, splanchnic and spinal anesthesia to the rectal administration of ether and oil and to ethylene gas and its administration. Among others is a discussion on excision of the lobe of the lung on apicectomy for collapsing a tuberculous cavity and a description of operations for removal of intrathoracic tumors and for repairing a hernia of the lung. There are chapters on operations on the heart, on the intestine and on the urinary tract on the prostate and the seminal vesicles, for undescended testicle on operations on the blood vessels and sympathetic nervous system on ganglions, a chapter on suture and ligature materials and one on the postoperative care of surgical patients. The volume is well illustrated. It closes with an index to volume VII and a separate general index to volumes I to VI.

Cardiovascular Pain as a Biochemical Problem. By Gordon Lambert, B.A., M.D., B.C., Senior Hon. Physician and Physician in Charge of Electrocardiographic Department, Royal Berkshire Hospital. With a foreword by Maurice Alan Cassidy, C.B., M.A., M.D., Physician Extraordinary to H.M. The King. Boards. Price 6s. Pp. 75 with 23 illustrations. London: H. K. Lewis & Company Ltd., 1933.

Lambert makes no claim that he has settled the question of anginal or, as he prefers to call it, cardiovascular pain. His object is to show the weak spots in the prevailing theories and to urge a greater concentration of investigation on the possibility or the probability, of a chemical explanation. He asserts that investigations based on morbid anatomy have not solved the problem though he does not go so far as to rule out pathologic conditions of the heart and aorta as having something to do with the production of pain. The logic of the author is often loose. His pages contain too frequently such expressions as 'impression', 'suspicion', 'assumed', 'one ventures to suggest', 'doubtless', 'perhaps'. In other words there is a lack of proof based on clinical, anatomic or laboratory facts that seriously detracts from the value of the work. One may agree with the laudable desire to stimulate study directed along biochemical lines but such work must be done in a more scientific manner than that manifested in the writing of this monograph. The expressed and veiled criticisms contained in the foreword by Maurice Alan Cassidy are sensible and to the point.

Medizinische Praxis. Sammlung für ärztliche Fortbildung. Herausgegeben von Prof. Dr. L. R. Grote, Chefarzt der C. von Noorden Klinik, Frankfurt a. M., Prof. Dr. A. Fromme, Direktor der chirurgischen Abteilung des Stadtkrankenhauses Dresden-Friedrichstadt, und Prof. Dr. E. Warnekros, Direktor der Staatlichen Frauenklinik zu Dresden. Band VI. Chirurgische Tuberkulose. Von Dr. med. Max Flesch, Thebesius, leitender Arzt der chirurgischen Abteilung am Privatkrankenhaus Sachsenhausen, Frankfurt a. M. Mit einem Geleitwort von Prof. Dr. V. Schmieden, Direktor der chirurgischen Universitätsklinik Frankfurt a. M. Paper. Price 15 marks. Pp. 194 with 58 illustrations. Dresden & Leipzig: Theodor Steinkopff, 1933.

The monograph 'Surgical Tuberculosis' by Dr. Flesch-Thebesius is one of a series of medical monographs comprising *Medizinische Praxis*. This book deals especially with bone and joint tuberculosis. Tuberculosis of the lungs, abdomen and genito-urinary tract are covered in other monographs. The author calls attention to the fact that formerly under the general heading of surgical tuberculosis were included those types of tuberculosis which were considered amenable to surgical treatment in short, surgery of the bones, glands, intestine

and genito urinary system in contradistinction to tuberculosis of the lungs, in which surgery was presumably of no avail. With the improvement in methods of conservative treatment, tuberculosis of the bones and joints is rapidly becoming the nonsurgical type of tuberculosis, while at the same time the improvement of surgical collapse therapy has changed the treatment in pulmonary tuberculosis from medical to surgical in a large proportion of cases. The author of this book on surgery of the bones and joints feels that both medical and surgical treatment have their place. He has, however, retained for the title of his work the old name surgical tuberculosis. He has derived his knowledge of the subject he is writing on from experience in the clinic, the sanatorium and private practice, and therefore he appreciates the advantages and the limitations of each of these three institutions. The book is written especially for the general practitioner and every effort is made to prescribe such therapy as the general practitioner can carry out. A particular point has been made in trying to answer some of the knotty questions frequently proposed to the man in general practice for example the relationship between trauma and tuberculosis of the bones and joints. These questions have been answered in a way that will help the general practitioner to reply to similar questions from his patients. The book is well illustrated is short and concise and will probably appeal to German speaking physicians either in industrial or in general practice.

Flynn of the Inland By Ion L. Idriess. With forewords by Sir Sidney Kidman and Ronald G. Macintyre. C.M.G. O.B.E. D.D. Sixth edition. Cloth. Price 8/- Pp 306 with 35 illustrations. Sydney Australia. Angus & Robertson Ltd. 1932.

This is a true story entertainingly written of the great effort of John Flynn to serve the inhabitants of the sparsely settled inland empire of Australia, the lonely prospector the ranchman and the children of these people. That vast land of good country and poor awaits the release of untold mineral and agricultural riches its people are isolated in two tens and twenties, hundreds of miles from medical and spiritual aid. John Flynn dreamed of providing these settlers with some of the bare necessities of medical service. He spent years in the inland, coming out now and then to further the organization of the Australian Inland Mission and to lecture in cities to arouse interest in the welfare of these people. The mission established nursing homes and small hospitals. John Flynn has lived to see physicians summoned by radio and traveling great distances by airplane into the inland to attend these isolated people. A leaf from the diary of one of these flying doctors follows.

Flew "bush" to a locality where there was no landing ground. Advised patient's friends to take him by car to a meeting place thirty miles distant. Patient very ill but began to improve when we got him to Cloncurry Hospital.

Called by telephone two hundred and twenty three miles to baby with malaria fever. Quick flight.

Called by telephone one hundred and twenty miles found husband wife and two children under poor conditions in isolated situation. Parents simultaneously overcome by a melancholic form of insanity and had been found wandering at large in the bush. Advised removal to medical centre.

Called two hundred and twenty three miles. Bumpy flight. Saw woman suffering from malaria. Other cases baby two sick women aboriginal with septic hand Japanese with synovitis contusions of foot and leg.

Called one hundred and seventy five miles. Swift flight—clear day. Baby fifteen months acute enterocolitis (?) meningitis. Transported to hospital. Patient's condition apparently not adversely affected by flight.

Advised man by letter re tumor on face.

Advised Mornington Island by wireless re patient suffering from skin rash.

Heard of man suffering from fracture of humerus. Unable to go out owing to absence of pilot in Normanton. Advised taking patient to Burketown Hospital. Two days later flew to Burketown but patient had not arrived.

Advised Mornington Island by wireless—child suffering from epilepsy. Flew to Normanton on mail machine at request of local doctor who was absent. Good opportunity to demonstrate possibility of flying-doctor's co-operation. QANTAS generously gave complimentary ticket for trip.

John Flynn has been likened to Wilfred Grenfell, who has done similar things for the natives in the ice bound coast of Labrador. Like Grenfell Flynn has gone abroad to see what is being done for pioneers elsewhere. This book will interest people who live in large cities those who sometimes forget the stars and the moon and who sometimes fail to realize the value and interest of living in the great outdoors.

Time to Live Adventures in the Use of Leisure By Gore Hambridge. Cloth. Price \$1.50 Pp 144. New York & London. Whittlessey House. McGraw Hill Book Company Inc. 1933.

Who would not appreciate more "time to live"? Who would not enjoy, in the words of the subtitle of this book, "adventures in the use of leisure"? The author has painted an alluring picture of what, to him, constitutes the "life of Riley." He is plainly one of those primitive souls to whom a routine is stifling, he prefers the adventure of uncertainty, even if it includes hardship, to the monotony of security. He abandons—in these times—a job and a pay-check and takes to freelance writing, a precarious occupation at any time, as he knew when he took the step. For persons with his tastes, the life he describes is ideal—far from the madding crowd, in bucolic surroundings, living the simple life for all it is worth and getting the last ounce of savor out of it. Of course, there are those to whom such a life would not appeal, who would feel as seriously bored in the rural scene as he felt confined and stifled in urban environment. Each to his taste. Regardless of the kind of surroundings a given person may prefer, there is much to be learned from Mr. Hambridge's plea that we take time to live, to play to enjoy handicraft, gardening, painting (even if we daub) and companionship of our loved ones. He would make life more of an art and less of a business. To him the five hour day and the five day week, or even less spell opportunity and time to live even if they may require us to lop off some of the so-called trimmings of civilization and get down to essentials, even to working again with our hands. Machinery is to him nothing more than an opportunity to get time for handicrafts. He paints a fascinating picture. We know that we ought to take his advice, but probably we shall just pass a delightful hour reading and approving his philosophy and then with a sigh go back to the same old treadmill.

A Further Study of Dental Clinics in the United States By Miriam Simons Leuck of the Research Staff of the Committee on the Study of Dental Practice of the American Dental Association. Statistical Adviser Charles A. R. Wardwell Assistant Professor of Statistics and Finance Northwestern University. Publications of the Committee on the Study of Dental Practice of the American Dental Association No. 4. Paper. Price \$1.50 Pp 178. Chicago. University of Chicago Press. 1932.

This publication of the Committee on the Costs of Medical Care presents an analysis of clinics for the care of the teeth in association with hospitals, industries, schools and dental schools. Most of the information contained was developed by the questionnaire method. It is recognized that dentists in private practice are confronted with the same problems that concern physicians so far as relates to the operation of dental clinics. Because the information developed is rather inadequate the book serves largely merely to indicate the nature of the problem and its extent without offering opportunity for definite conclusions. Apparently there are 1,933 dentists employed in various dental clinics. They work for salaries, although in large clinics much of the service is donated by volunteers. Most dental clinics are, of course, located in metropolitan centers. In these clinics there is an additional thousand employees who are not trained as dentists but who aid in the work. During 1930 the clinics cared for approximately a million and a half of people. The clinics seem to be increasing at a rate which will involve the treatment of three million patients in 1938. All types of dental service are rendered. It is found that dentists working for clinics have median net earnings of approximately \$2,848.00 a year, or \$1,246.00 less than that of a median dentist in private practice.

Studies on the Nutritive Value of Milk. II The Effect of Pasteurization on Some of the Nutritive Properties of Milk By W. E. Krauss J. H. Erb and R. G. Washburn. Bulletin 518. Paper. Pp 23 with 8 illustrations. Wooster Ohio. Agricultural Experiment Station. 1933.

This bulletin includes a review of the literature and the experimental procedure followed in the study of the effects of raw and pasteurized milk on anemia development, growth and calcification in albino rats and the influence of pasteurization on vitamins A, B, D and G and curd tension. Albino rats developed nutritional anemia at the same rate when fed exclusively on raw or pasteurized milk. No loss of iron or copper occurs during pasteurization of milk. When milk fortified with copper and iron exclusively to eliminate the anemia factor is fed, no significant difference is apparent in the total

nutritive effect of raw or pasteurized milk. The calcium and phosphorus in the two forms of milk are equally available. Pasteurization does not affect vitamins A, D and G but does destroy at least 25 per cent of the vitamin B originally present. Pasteurization slightly reduces the curd tension of milk. The nutritive deficiencies of pasteurized milk, vitamins B and C, can be readily overcome by proper dietary control. The continued use of pasteurized milk offers no serious problem from the human standpoint.

Diseases of the Eye Practitioner's Series By Andrew Rugg Gunn M.B. F.R.C.S. Surgeon to the Western Ophthalmic Hospital. Cloth Price 12s 6d. Pp 188 with 34 illustrations. London: William Heinemann Ltd. 1933.

This brief textbook treats of ophthalmology from the point of view of familiarizing the physician with the essential diseases of the eye that he will be called on to take care of in the course of his daily routine. The subjects covered are essentially conjunctival inflammations, the commoner inflammations, iritis, syphilis of the eye, cataract, glaucoma, the commoner tumors of the eye, the type of retinitis seen with general disease, and the various ocular palsies. For the scope intended, the book is quite sufficient. It does not discuss refraction or surgery and for that reason it would not serve as a textbook for the beginning ophthalmologist. It compares favorably with similar books on the subject.

Foreign Bodies and the Doctrine of Res Ipsa Loquitur

(Pendergraft v. Royster (N. C.) 166 S. E. 285)

The plaintiff sued the defendant alleging that after an operation he left in her body a glass drainage tube which had been broken or at the time of dressing her wound used gauze packing which had embedded in it broken pieces of a glass tube, which, on the removal of the packing, were allowed to remain in her body. The defendant had operated on her, Jan. 24, 1929, to cure certain conditions among them a misplaced uterus and lacerations of the cervix. According to her testimony she made a good recovery and was well satisfied with her condition when, on or about April 28, next following the operation, while she was working in her garden, a pain struck her, seemingly, she said, in the very bottom of my stomach. She sat on the edge of a chair, placed her finger on the mouth of her womb, felt a foreign substance there and with difficulty removed it. It was, she testified, a piece of glass almost an inch long with jagged ends, and it looked like it had been part of a tube. Her husband said it was part of a glass tube and the end tapered like a pen point. About a month later, plaintiff testified, a piece of glass was discharged at the time of menstruation, and three or four more times during the year following the operation pieces of glass came away. So far as the published record shows the plaintiff introduced no evidence to prove the presence in the operating room of a glass drainage tube at any time during the operation or to show the presence of glass on the gauze to be used for packing. The defendant, however, while denying the plaintiff's allegations of carelessness and negligence, said that in irrigating the site of the operation he used a glass nozzle attached to the end of a rubber tube. He was certain, however, that no part of the nozzle had been broken off. He denied that there was any glass in the gauze which he had used. He was unable to account for the presence of glass in the plaintiff's body. Catgut comes in little glass tubes, he testified, but the tubes are broken by nurses before the operation is started. If an extra supply is needed in the course of an operation, a tube may be broken in the operating room, but it is not broken around or near where there is gauze for packing. It is broken at a different table on the opposite side of the room. These tubes are broken between layers of towels or layers of gauze, and if gauze is used it is thrown into the waste basket. If there had been any glass on any of the gauze used for packing, any one using the gauze would have seen the glass and would not have used the gauze. A tube containing catgut was broken in the presence of the jury, and the plaintiff selected a piece of

the broken tube, which, she testified, corresponded very closely to the piece of glass that she took from her body. The correctness of the defendant's procedure in the course of the operation, its conformity to standard good practice in the community where the operation was done, and the improbability of glass having been introduced into the uterus in the course of the operation and remaining there as long as was alleged in this case, were testified to by expert witnesses appearing on behalf of the defendant. Judgment was given in favor of the patient, however, and the defendant appealed to the Supreme Court of North Carolina.

No presumption of negligence, said the Supreme Court, arises from a physician's error of judgment in the diagnosis of a case or from his failure to cure, or to accomplish results as good as some one else might have accomplished, except where there is manifest such obvious gross want of care and skill as to afford, of itself, an almost conclusive inference of negligence. *Slimak v. Foster*, 138 A. 153, *Donahoo v. Lovas*, 288 P. 698. In such cases, neither affirmative proof of negligence nor expert testimony as to the defendant's want of skill need be given on behalf of the plaintiff. The proved facts are accepted as a sufficient basis for a presumption of negligence, under the doctrine of *res ipsa loquitur*. The casualty itself and the circumstances surrounding it may furnish all the proof that the injured person is able to offer or that it is necessary to offer. Where the injury is received while the patient is unconscious, the doctrine of *res ipsa loquitur* is commonly held to apply, because under such circumstances the patient is unable to testify as to what happened, whereas the physician can do so. Herzog's Medical Jurisprudence, section 187 note, 162-163. In operations like the present one, the patient is unconscious, and if the doctrine of *res ipsa loquitur* did not apply, the patient would be without a remedy.

The defendant, however, contended that the application of the doctrine of *res ipsa loquitur* was not justified in the present case, because he had denied that the alleged injury to the patient had been caused by glass left in the operation wound. Before the doctrine became applicable in this case, he contended, the patient had to prove her alleged injury had been so caused. This contention, however, the Supreme Court rejected, quoting with approval from the charge given to the jury by the trial court:

Where a thing which causes injury is shown to be under the management of the defendant and the accident is such as in the ordinary course of things does not happen if those who have control and management of it use the proper care, it furnishes or would be some evidence, in the absence of explanation of the defendant that the accident arose from want of care. The principle of *res ipsa loquitur* (which means the thing speaks for itself) in such cases carries the question of negligence to the jury, not however relieving the plaintiff of the burden of proof and not raising any presumption in her favor but simply entitles the jury in view of all the circumstances and conditions as shown by the plaintiff's evidence to infer negligence and say whether upon all the evidence the plaintiff has sustained her allegation.

Although the defendant and his witnesses contended that the injury alleged could not have occurred in the manner claimed by the plaintiff, the issue was a matter of fact to be determined by the jury. The evidence adduced was sufficient to be submitted to the jury, and the jury, not the court, are the triers of disputed facts.

The judgment in favor of the patient was affirmed.

COMING MEETINGS

American Association of Railway Surgeons, Chicago, August 10-12. Dr. Louis J. Mitchell, 29 East Madison Street, Chicago, Secretary.
Idaho State Medical Association, Yellowstone National Park, August 6-8. Dr. Harold W. Stone, 105 North Eighth Street, Boise, Secretary.
Maine Medical Association, Poland Spring, June 26-28. Dr. Philip W. Davis, 22 Arsenal Street, Portland, Secretary.
Montana Medical Association, of Anaconda, July 12-13. Dr. E. G. Balsam, Box 88, Billings, Secretary.
National Tuberculosis Association, Toronto, Canada, June 26-30. Dr. Charles J. Hatfield, Seventh and Lombard streets, Philadelphia, Secretary.
Pacific Coast Oto-Ophthalmological Society, San Francisco, June 28-30. Dr. F. C. Cordes, Fitchburg Building, San Francisco, Secretary.
Western Branch Society, American Urological Association, Vancouver, B. C., August 3-5. Dr. George W. Hartman, 999 Sutter Street, San Francisco, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Results of Sympathectomy—Adson feels confident that sympathectomy, in its various forms will continue as a means of treatment in conditions of dysfunction of blood vessels, smooth muscle and glands. Progress in this field requires the cooperation of the anatomist, the physiologist and the clinician. It would be unwise for the surgeon to attempt operations on the sympathetic system unless he is thoroughly familiar with the anatomy. Most satisfactory results have been accomplished by sympathetic ganglionectomy and trunk resection in the treatment of peripheral vascular diseases such as Raynaud's disease, thromboangiitis obliterans with vasomotor spasm of the collateral arteries, acral scleroderma developing subsequent to Raynaud's disease and periarticular arthritis in the hands and feet associated with vasospastic phenomena of cold, clammy, pale and cyanotic extremities. The sectioning of sympathetic fibers to the internal sphincter muscles of the rectum and bladder, and of sympathetic fibers carrying inhibitory impulses to the large intestine and to the detrusor muscles of the bladder, has materially aided the expulsive forces of both the rectum and bladder, thus offering assistance in the treatment of congenital megacolon and cord bladder.

Hepatic Cirrhosis—Althausen states that the earliest lesions leading to experimental cirrhosis of the liver are always found in the hepatic parenchyma. Any toxic agent causing necrosis of the parenchymatous cells of the liver will on repeated administration produce cirrhosis of this organ. He discusses alcohol and inert colloids as etiologic factors in cirrhosis. Following necrosis of hepatic tissue regeneration of parenchyma and proliferation of the framework of the liver take place. The relative prominence of these two processes as well as the dose of the toxin and its chemical nature, determine the clinical and pathologic end picture of cirrhosis. The unitary conception of the genesis of the various types of cirrhosis of the liver furthers earlier recognition and treatment of this disease by focusing attention on the toxin involved.

Cardiac Complications of Hyperthyroidism—Smith and Sauls present the histories of four patients with hyperthyroidism and unusual cardiac complications. It is necessary to suspect hyperthyroidism in some patients with heart disease. To suspect thyrotoxicosis in the absence of physical signs is essential in making a diagnosis in these obscure cases. Attempts should be made to elicit a history of nervousness, palpitation

of the heart, loss of weight, diarrhea of inexplicable origin, excessive sweating, premature gray hair, preference of cold to hot weather, and familial occurrence of hyperthyroidism. On close questioning, a history of hyperthyroidism with a spontaneous remission many years before may be obtained. In treating these patients, iodine should almost never be given unless plans for operation have been made. Preoperative preparation should consist of complete rest in bed, forced feedings and large doses of sedatives. After from ten to fourteen days of iodine administration the patient's general condition will usually be much improved and the metabolic rate consequently greatly reduced. Operation can then be performed without difficulty.

- *Diagnosis of Uterine and Tubal Pathology Using Lipiodol. A T Harris Sheldon Iowa.—p 146

Diagnosis in Spondylolisthesis—Meyerding states that, of the 207 patients with spondylolisthesis examined at the Mayo Clinic, 64 per cent were hard-working people. Their average age was 40 years, and 71 per cent were men. The principal

complaint was backache of almost nine years duration. Although many patients had consulted physicians, and roentgenograms had been made, less than 10 per cent had been given a diagnosis. Symptoms are relieved by rest but hard work, especially stooping and lifting aggravate them. The patient may appear well and be gaining in weight. The anteroposterior roentgenogram may appear to be negative. Malingering may be suspected when the subluxation is slight and discernible only in lateral roentgenograms. Clinical signs vary with the degree of deformity. A typical example discloses depression or lordosis of the lumbar spinous processes with prominence of the fifth lumbar spinous process and the sacrum. This region was involved in 86 per cent of the cases. With increased subluxation shortened torso and broadened pelvis occur. Motion of the spinal column is principally limited on forward bending. Although trauma is significant as an etiologic factor, it may be difficult to prove. The history and clinical data when substantiated by evidence of fracture in the roentgenogram, are conclusive. Symptomless spondylolisthesis occurred in 9 per cent of the cases. A hard bony mass is sometimes palpable low in the abdomen. Rectal examination, protoscopic or manual, may disclose a narrowed anteroposterior diameter of the pelvis. In about 2 per cent of the cases the spondylolisthesis was of the reverse type. Congenital anomalies were present in a high percentage of cases. Spondylolisthesis is seldom recognized in general practice. It is obviously associated with chronic backache. Roentgenologists may disclose its presence in spite of negative clinical data. One may look forward to an increasing incidence of this deformity in cases of chronic backache and injury to the spinal column as a result of the more common use of lateral roentgenograms of the lumbosacral area.

Prevention and Treatment in Uterine Cancer—Shroyer believes that the majority of women complaining of nervous disorders, general tiredness, backache, mental irritation, leukorrheal discharge, constipation and palpitation of the heart are affected by toxic poisons generally from the pelvic organs. These patients usually have a congested liver and will feel better at once if given mercurous chloride followed by magnesium sulphate next morning. All cancer patients present these complaints and frequently admit that they have been getting worse each year. The author has seen patients who have been treated for heart disease for several months. When they are examined (and thyroid disease is absent) often the real underlying cause has proved to be a lacerated cervix with accompanying gallstones. Why should not these patients develop cancer with such bombardment of bacterial and chemical toxins? The intestinal tract should be cleaned up with proper foods and all points of infection and irritation should be removed. One should not wait and watch a condition to see what the outcome will be but should institute the most scientific treatment available. By doing so one will be able to prevent many an individual from becoming a victim of cancer. Total or subtotal hysterectomy should never be performed for menorrhagia. Radium will cure these cases, it not only destroys cancer cells but kills the infection present. If the hemorrhage is not corrected operation is in order after several irradiations and few patients will die following the operation. The author irradiates all myomas and fibroids except those that are pedunculated and calcified, and, if necessary, he operates two or three months later.

Diagnosis of Uterine and Tubal Pathologic Disorders—Harris points out that, in the more obscure uterine and tubal pathologic changes, the most successful means of establishing a diagnosis, without resorting to laparotomy with its dangers and discomforts is through the use of iodized oil to assist in the roentgenographic visualization of the organs of reproduction. Iodized poppy-seed oil is ideal in that there are no contraindications—no open blood channels such as are seen in malignant conditions and menorrhagia. He concludes that uterosalpingography is an unrivaled means of establishing a diagnosis of uterine and tubal abnormalities that cannot be detected with any degree of certainty except by laparotomy and is an accurate means of diagnosing the cause, or causes, of sterility in women otherwise normal and having normal husbands. Uterosalpingography is a most useful aid in establishing with certainty, with little or no risk to either the mother or the embryo, the presence of the earliest stages of pregnancy.

- Teaching of Practical Obstetrics. D. Dougal.—p. 99

Puerperal General Peritonitis—Pyrah and Oldfield state that puerperal general peritonitis is present in about one half of all patients who die from puerperal fever. In most of these cases it is the immediate cause of death. Puerperal peritonitis is caused in the majority of cases by the streptococcus and has been assumed to be almost uniformly fatal. The most severe cases arise within the first four days after delivery and follow the rapid invasion of the peritoneal cavity by organisms entering through the lymph node vessels in the wall of the uterus. There is often a blood infection and rarely any localized pelvic suppuration. General peritonitis occurring four days or later after delivery is less severe, and in these patients localized pelvic suppuration is most commonly found in the wall of the uterus and less frequently in the ovary and in the broad ligament. The peritoneal infection may arise either from the uterus itself or more often from the localized abscess. The authors outline other causes of peritonitis occurring in the puerperium and describe the symptoms and signs of acute puerperal general peritonitis. They urge that operation for cases in which puerperal peritonitis is reasonably suspected should be undertaken much more often than it has been in the past. The fully developed clinical picture must never be awaited if the present high mortality is to be reduced. Although diagnosis is always difficult, they think that most cases may be recognized before the peritoneum is widely affected. Cases of puerperal sepsis in which a palpable mass is present must be watched for signs of involvement of the general peritoneal cavity, and, if such an involvement is diagnosed, immediate operation must be performed. An abscess of the wall of the uterus is especially liable to be associated with general peritonitis. The authors report a series of thirty-six cases of puerperal general peritonitis, with recovery in eleven.

- *Note on Some Experiments on Action in Vitro of Normal Human Serum on Trypanosoma Brucei and T. Rhodesiense. J. F. Corson.—p. 53

Experiments with Trypanosoma Brucei and T. Rhodesiense—Corson records experiments made with two strains of Trypanosoma brucei and one strain of T. rhodesiense. The object of the experiments was to see if guinea-pig serum had any trypanocidal action on T. brucei. Shinyanga, if the serum of a rat that had previously resisted infection with T. brucei. Natal was trypanocidal to it, and if the strain of T. rhodesiense, freshly isolated from man, was resistant to human serum. It was found that the guinea-pig serum had no apparent trypanocidal action on T. brucei. Shinyanga and that the serum of the resistant rat also had no trypanocidal action on T. brucei. Natal. Both strains of T. brucei were susceptible to normal human serum, as was also the strain of T. rhodesiense. The resistance of guinea-pigs and of some white rats to the two strains of T. brucei does not seem to be connected with any trypanocidal action of their serum. The apparent susceptibility of the strain of T. rhodesiense to the serums of two native men belonging to an area free from trypanosomiasis, does not lead one to think that inoculation of the donors of the serum with the blood of the rat would fail to infect them. The little evidence that exists at present on this point is rather against that supposition but experiments on man would seem to be necessary to decide the question.

Hemorrhagic Pleurisy with Eosinophils in Cancer of Lung—Bernard and Marie affirm the existence, contrary to classic opinion, of hemorrhagic pleurisies with eosinophils during the course of primary cancer of the lungs. These neoplastic pleurisies with eosinophils present two varieties. In one type the pleurisy is abundant and the eosinophilia is distinct and is the only distinguishing feature characterizing this type of effusion. The other type is characterized by its insidiousness, the slight amount of the effusion, its enormous and transitory eosinophilia, its short duration and its aseptic nature. This micropleurisy with eosinophils, whether it is hemorrhagic or citrine, appears to translate a special process of aseptic reaction to the pleural serosa which may be realized by different causes, such as pulmonary neoplasia, acute pulmonary congestion, endocarditis, or pulmonary amebiasis.

Genital Passages of Women J. Seguy and J. Vimeux.—p. 346

Ascent of Spermatozoa in Genital Passages of Women.—Seguy and Vimeux found that the acidity which normally exists in the vagina stimulates the spermatozoa and increases their oscillations, but it also shortens their existence so that, contrary to accepted opinion, those which do not leave the vagina rapidly are killed. The cervical content is always alkaline and strongly attracts the spermatozoa, which cannot penetrate the orifice of the cervix unless it contains an abundant quantity of a glairy, fluid, transparent secretion. The glairy secretion that makes the cervix permeable is physiologic and temporary and is probably linked to the phenomenon of ovulation. It may appear at different periods of the menstrual cycle and its duration is variable. In most women this permeable glairy secretion is present only once during the menstrual cycle, it appears about the tenth day after the beginning of the previous menstrual period and lasts from four to five days. In some women the cervix is never physiologically permeable to spermatozoa because there is no secretion, because it is too scanty or because it is purulent. These facts make it possible to understand certain cases of unexplained sterility.

*Streptococcic Septicemia with Port of Entry in Genital Organs Causing Encephalitic Syndrome Case E. A. Beretervide and J. J. Reboiras.—p. 686

Streptococcic Septicemia with Port of Entry in Genital Organs—Beretervide and Reboiras state that streptococcic septicemia has a sudden onset with chills, high fever, intense headache, nausea and vomiting associated with a nervous syndrome, which later is complicated with cardiac disturbances. The blood presents a typical picture with leukopenia, granulocytopenia and bacteremia. Endocarditis is the most frequent and the gravest complication. Streptococcic septicemia varies with the character of the infection. Benign forms are rare and may be cured. The differential diagnosis is made with typhoid, acute tuberculosis, undulant fever, malaria and other forms of septicemia. Fixation abscess and the treatment of local foci of infection are the most promising therapeutic methods. Transfusion and immunotransfusion may give satisfactory results but serums and vaccines do not. The authors' patient aged 12 presented a syndrome of encephalitis with mental confusion and

delirium. An intense suppurative vulvovaginitis of infectious origin and of long duration proved to be the source of the streptococcic septicemia. The infection that originated the vulvovaginitis was typhoid, from which the child had suffered some years before the actual disease. Eight days of treatment of the vulvovaginitis with methenamine intravenously and orally produced a great improvement in the patient's general condition. The mental confusion, tachycardia, hypertonia and fever still persisted, although slightly modified. No nervous symptoms were observed after two months of treatment. The cardiac complications, represented by insufficiency of the mitral valve, seemed to be a permanent sequel. Multiple small subcutaneous abscesses appeared in different parts of the patient's body.

*Treatment of Constipation by Resection of Lumbar Sympathetic. J. Diez.—p. 767

Gastric Aleukemic Lymphomatosis in Children.—Cibils Aguirre and his collaborators state that the development of gastric tumors during childhood is rare. They report a case of aleukemic lymphomatosis localized in the stomach of a child, aged 12, in whom the diagnosis was made during the life of the patient. At first a clinical diagnosis of either Pott's disease or neuropathy was erroneously made. A diffuse gastric tumor, the nature of which could not be determined, although its roentgen characteristics were similar to those given by gastric cancerous tumors, was discovered by roentgen examination. At operation a diffuse gastric tumor with great lymphatic infiltration was found. The tissues of the stomach were friable, making impossible any attempt at performing a gastrectomy or gastroenterostomy. An ileostomy was performed. The authors' case is the first in the literature in which an extensive roentgen study of the disease has been reported. There are no typical roentgen characteristics of lymphoblastoma. Nevertheless, the authors say that some writers attach importance to the persistence of peristalsis to indicate the presence of gastric lymphoblastoma, as differentiated from carcinoma, in which peristalsis disappears, that a differential diagnosis between gastric lymphoblastoma and gastric polyposis may be made by pneumogastroenterography, and that the roentgen aspect of lymphoblastoma shows a moderate infiltration of the tissues if compared with the more destructive character of lymphosarcoma. The differentiation of the nature of gastric tumors by roentgen examination is important because on this differentiation depends the nature of the treatment (surgical or roentgen) to be used. Roentgen irradiation has a favorable action on gastric lymphoblastoma. The authors advise making a revision of the clinical conception and terminology of gastric aleukemic lymphomatosis to establish a more proper and clearer classification in relation to the anatomic and hematologic aspects of the disease.

Treatment of Constipation by Resection of Lumbar Sympathetic.—Diez states that surgery of the sympathetic nervous system has great advantages over other surgical methods used heretofore for the treatment of constipation. The technique of the operation is simple. The author follows the extraperitoneal route of approach. The superior and inferior sections of the sympathetic lumbar nerve are made at the level of the first and fourth lumbar vertebrae, respectively. Whether the sympathetic lumbar nerve is sectioned at the right or at the left side, the results of sympathectomy are the same, since the sympathetic innervation of each segment of the intestine is bilateral. The aim of lumbar sympathectomy is to cause the surgical destruction of the sympathetic nervous fibers, which cause the functional inhibition of Auerbach's plexus, and to leave intact the parasympathetic nervous fibers, which stimulate the functions of the same plexus. The complete predominance of parasympathetic over sympathetic influences in Auerbach's plexus produces increased peristalsis of the distal segment of the colon, increased tonus of the intestinal musculature and diminished control of the internal sphincter of the anus, all of which result in the correction of constipation. The functions of the colon are not modified immediately after the operation. Spontaneous evacuation appears from six to eight days after

the operation, and the daily evacuation is normal from twenty to thirty days after the operation. The size and length of the colon decrease slowly but continuously so that three months after the operation roentgen examination shows the favorable modifications which the organ has undergone as a result of the operation. Copremia and the painful symptoms of the right segment of the colon disappear with the disappearance of constipation and the patient shows marked improvement. If no satisfactory results are obtained from unilateral lumbar sympathectomy, it is advisable to repeat the operation on the opposite side, since it is simple and does not endanger the patient in any way. The shock caused by the operation is not greater than that caused by any other surgical intervention such as appendectomy. The operation is performed in about twenty minutes. While other methods previously reported for the correction of constipation aimed at correcting only the anatomic abnormality coexistent with the pathologic condition by suppressing the functions of the pathologic organ or by removing the organ sympathectomy aims directly at correcting the disequilibrium that exists between the sympathetic and parasympathetic influences governing the functions of the organs, without altering or removing the pathologic viscera.

Hormone of Parathyroids in Blood of Pregnant Women.—The starting point of Hoffmann's investigations was a number of clinical and experimental observations indicating increased functional activity of the parathyroids during pregnancy. He attempted to solve this problem by the direct demonstration of an increased content of parathyroid hormone in the blood of pregnant women. Since thus far the parathyroid hormone had been isolated only from the parathyroids, it was necessary to devise a new method for its isolation from the blood. The principle of the method is the separation of the active substance from the serum protein bodies by boiling with diluted solutions of hydrochloric acid and by subsequent filtration. Further refinement of the hormone is obtained by treatment with dilute solution of acetone and by precipitation with dilute solutions of trichloroacetic acid. The dry residue of this precipitate is further purified and following neutralization is dissolved in physiologic solution of sodium chloride for testing. A quantity of 100 cc of plasma yielded generally from 20 to 30 mg of the hormone as dry residue. The action of the preparations obtained from the blood of pregnant women was tested by determining its influence on the calcium content of the blood of dogs. The amount obtained from 75 cc. of plasma withdrawn during the last stage of pregnancy resulted in a comparatively rapid increase in the calcium content of the blood. In comparing the calcium mobilizing substance of the blood of pregnant women with the parathyroid hormone it was found that the two substances were identical not only in regard to their pharmacologic but also to their essential physical and chemical properties. In systematic tests on the parathyroid hormone content of the blood during pregnancy and during the puerperium it was found that the hormone was present in sufficient quantities for detection between the third and fourth months increased slightly up to

the eighth and was greatly increased at the end of pregnancy. During the puerperium the hormonal content decreased rapidly.

Therapy of Irregularities of Ovarian and Hypophyseal Functions.—Louros says that so many factors are involved in the abnormal function of the ovaries and of the hypophysis that it is frequently difficult to determine the efficacy or the failure of the hormone therapy. Observations on 700 patients with abnormal ovarian activity convinced him that there are certain prerequisites for the success of the hormone treatment. He found hormone therapy entirely valueless in the presence of abnormal anatomic conditions of the ovaries and of the uterus. Ovarian cysts, tumors of the uterine adnexa, chronic inflammations, adhesions and anomalies in the position of the uterus must first be corrected by surgical intervention before hormone therapy can be commenced. A persisting corpus luteum was found to be the cause of the abnormal ovarian function in some cases, and the author considers it noteworthy that a tuberculous process existed in the three patients in whom this was the case. He discusses the indications for hormone therapy. In irregularities of menstruation in which the rhythm and the cyclic character are still preserved but in which the duration and the quantity of the flow are subnormal, the ovarian hormone should be administered, provided the local anatomic conditions are normal or have been surgically corrected. The symptoms of abolished function, such as dizziness, headaches, hot flashes, palpitation of the heart, articular pains, cutaneous paresthesias, perspiration itching and psychic disorders, which may occur with or without the aforementioned menstrual disturbances, yield to ovarian hormone therapy as do also dyspareunia or sterility, provided there is no irregularity in the menstrual period. In menorrhagia, a local cause should always be searched for, the operative removal of which usually reestablishes the normal period, so that hormone therapy is not required in these cases. If the menstrual period is so irregular that the cyclic rhythm is no longer detectable, hypophyseal and ovarian preparations should be given after local disturbances have been ruled out. A pulmonary tuberculosis is a contraindication to any therapy that aims to reestablish the ovarian function, for in these cases the cessation of the menstrual flow is a compensatory action on the part of the organism. The author states that the oral administration of ovarian preparations is generally of little avail and he recommends that they be given intravenously. Hypophyseal hormone is administered intramuscularly. Treatment with calcium preparations proved a valuable adjuvant to hormone therapy, probably because of its action on the sympathetic

Short Wave Therapy in Gonorrheal Arthritis.—Graf points out that the short wave method introduced into medicine by Schliephake is acquiring a permanent place in the therapeutic armamentarium. It employs wavelengths of from 20 to 3 meters in the air condenser field, and some authorities refer to these waves as the "ultrashort." The author employed short waves of a length of from 19 to 14 meters, according to Schliephake's method in nine cases of gonorrheal arthritis, with rapid alleviation of the pains which in most cases disappeared entirely. The other manifestations of inflammation likewise decreased. The author recommends short wave therapy as an effective therapy of gonorrheal articular inflammations.

Superinfection with Syphilis During Bismuth Therapy.—Zetterholm relates the clinical history of a man aged 48, in whom, following renewed exposure to syphilis, signs of a reinfection appeared in spite of the fact that he still received bismuth compounds. This observation induced the author to study the literature about reinfections. Among 630 cases he found only six in which reinfection took place during the treatment of the first infection. The antisyphilitic remedies used in these cases of unsuccessful prophylaxis were mercury preparations and arsphenamine. The author considers the reported case of interest in the discussion of the prophylactic value of bismuth and he also mentions one publication which reports that five prostitutes became infected in spite of prophylactic bismuth therapy.

Atypical Forms of Dementia Paralytica.—Saethre points out that a negative Wassermann reaction in patients with untreated dementia paralytica is rare. Among 135 such patients, he observed four in whom the Wassermann reaction was negative in both the blood and the cerebrospinal fluid, three in whom the cerebrospinal fluid gave a negative reaction while the blood was positive, and one in whom the blood gave a negative and the cerebrospinal fluid a positive reaction. In all untreated Wassermann negative cases, the cerebrospinal fluid showed all the other symptoms that are typical for dementia paralytica, including the colloidal gold and mastic reactions. The author discusses particularly the four cases in which the Wassermann reaction was negative in both the blood and the cerebrospinal fluid. In one of these patients the characteristic symptoms of paralysis had existed for a year. The anamnesis revealed that a cerebrospinal fluid test had been done in another clinic nine months previously and had been found positive. Since the patient had received neither malaria therapy nor any other specific treatment, the change in reaction had developed spontaneously. In a second patient of this group, the Wassermann reaction of the serum had been positive a year before. The third patient was admitted to the clinic with new symptoms of dementia paralytica with a negative Wassermann reaction in both the blood and the cerebrospinal fluid but with otherwise typical paralysis symptoms. In the fourth patient, the Wassermann reaction had been negative in four tests performed in the course of six months. All other observations on the cerebrospinal fluid were indicative of a typical dementia paralytica. Because the anamnesis revealed no syphilitic infection, because the pupillary reaction was normal and because the Wassermann reaction was constantly negative the case was not diagnosed as dementia paralytica but an encephalitis or a polysclerotic dementia was assumed and the patient was sent to a hospital for mental diseases. Here the dementia, ataxia and paralysis of the lower extremities increased rapidly. The patient died from pneumonia four years after the beginning of the dementia. The postmortem examination revealed changes indicative of dementia paralytica. The author relates a peculiar case of paroxysmal megalomania ('psychic jacksonian attacks') in a patient with tabes who had undergone malaria therapy.

Traumatic Paralysis.—Gallinek and Hennig discuss types of paralysis that constitute a unit on the basis of their etiology and symptomatology and refer to paralyzes in the region of the plexus brachialis and of the plexus sacralis which usually develop suddenly during exertion. Frequently they are preceded by a hasty movement and develop only while the body is burdened that is, while carrying lifting throwing or catching a heavy burden. The trauma consists in an injury to the roots of the plexus by an unsuitable movement or by continuous vibration and simultaneous exertion, as is the case in the use of tools operating with compressed air and repeatedly pressed against the shoulder. The prognosis of the described types of paralysis is unfavorable.

Extrapyramidal Attacks Following Antirabic Vaccinations.—Schindelmann's case was that of a boy, aged 8 who had previously suffered from attacks (epilepsy). Two weeks after completion of antirabic vaccination there developed in addition to involuntary myoclonic movements of the facial and cervical muscles a peculiar disturbance of the walking function. A normally begun movement was arrested suddenly, and this disturbance was accompanied by a disordered static function (falling of the patient). Simultaneously with the somatic dis-

turbances, changes appeared also in the character and intellect of the patient. The disturbances observed in this case differ from those occurring in chronic encephalitis only in that they were not continuous but intermittent. Complications in the form of involvement of the central nervous system are comparatively rare in antirabic vaccination. The Leningrad institute reports only five cases in 40,000 vaccinations. Some authors consider the complications as mild cases of rabies while others ascribe them to a virus fixé. The author is inclined to believe that the condition of the nervous system has a certain influence on the development of the antirabic complications for the patient observed by him had previously been subject to attacks that probably produced a predisposition for epilepsy.

Diagnosis of Nephrolithiasis.—Schmidt emphasizes that the general practitioner should be able to diagnose concretum formation in the urinary passages from the symptoms without roentgenologic examination and without probing of the ureters. He thinks that the patient should be subjected to a specialized roentgenologic and urologic examination only after the diagnosis has been made or after there is considerable evidence for it. The author discusses some of the pathologic factors of nephrolithiasis, namely the pathogenesis the types of persons in whom it occurs most frequently and the disorders with which it often concurs. He describes the spontaneous pains those elicitable by pressure their irradiation character, time of occurrence and course, and the factors that elicit them. As accompanying manifestations he mentions disturbances in the evacuation of the urine, nausea, chills, pain and eventually swelling of the testes symptoms in the homolateral leg such as cramps or weakness in the muscles of the calf, inflation of the abdomen, tension in the abdominal walls, and fever. Discussing the signs of nephrolithiasis detectable in the urine, the author mentions the precipitation of crystalline sediments and the turbidity of the urine which, although not immediately connected with nephrolithiasis nevertheless frequently occur with it and the occurrence of blood in the urine and oliguria. He advises palpatory examination of the kidney, auscultatory examination of the lumbar and flank regions, rectal and vaginal examination and examination of the abdominal reflexes.

Functional Test of Lung.—Klein and Nonnenbruch feel the lack of methods that permit a determination of the result of the pulmonary action namely, the arterialization of the blood. In trying to devise methods for this purpose, they had the following aims (1) to put the lung under conditions that represent a sort of tolerance test for the gas exchange in order to detect slight or latent disturbances, and (2) to detect objective values and to eliminate subjective factors. The first method described by the authors is a continuous control of the behavior of the oxygen saturation deficit in the arterial blood during and after short periods of nitrogen inhalation. The patient inhales nitrogen and by this a pure anoxemia without carbon dioxide stasis is produced. Blood is withdrawn from the radial artery before the nitrogen inhalation, at the end of seventy seconds of inhalation, and from twenty to thirty seconds after the inhalation. The three blood specimens are examined for oxygen deficit, oxygen capacity, oxygen content and percentage of saturation. In patients without pulmonary and circulatory disturbances the anoxemia has disappeared again from twenty to thirty seconds after the nitrogen inhalation, and the oxygen deficit has decreased to its initial value. In patients with dis-

turbances of the lung, such as pulmonary stasis, emphysema, kyphoscoliosis and compression atelectasis, the anoxemia is nearly as pronounced at the third withdrawal of blood (from twenty to thirty seconds after inhalation) as at the end of the inhalation and the oxygen deficit is likewise practically unchanged. The authors discuss another test in which histamine is employed. By arterial puncture, blood is withdrawn for analysis, and 1 cc. of histamine is injected subcutaneously. The second withdrawal of arterial blood takes place from twenty to twenty-five minutes after the histamine injection and the third blood specimen is taken from forty to forty-five minutes after the injection. The deficit and capacity, the saturation and the content of oxygen are then determined in the blood specimens by means of gas analysis. If the pulmonary function is normal, the oxygen deficit either does not change under the influence of histamine or the change amounts to only from 0.5 to 0.7 volume per cent. Since the oxygen capacity is nearly always increased by the action of histamine patients with normal pulmonary function never show a reduction in the percental oxygen saturation and in the absolute oxygen content, even if there is a slight increase in the oxygen deficit. On the contrary, an eventual slight increase in the oxygen deficit is always more than compensated by the increase in capacity so that, in case of normal pulmonary function, there is always an essential increase in the percental oxygen saturation and in the oxygen content. In patients with disordered pulmonary function (emphysema, pneumothorax, compression atelectasis, pulmonary stasis) histamine injection always effects an increase in the oxygen deficit of more than 1 volume per cent and, generally, from 2 to 5 volumes per cent and there is always a decrease in the percental and generally also in the absolute oxygen content. The authors emphasize that, if the time is limited, the nitrogen method should be used but in the case of sensitive patients the histamine method should be employed.

Expulsion Reflex of Urinary Bladder—Schlesinger points out that the onset of senility, particularly in men, is frequently accompanied by disturbances of micturition. Even if the prostate is normal the process of micturition may become impaired. The author found that by tapping or slightly rubbing the abdominal wall the onset of micturition can be accelerated. After apparent termination of the act a repetition of the described procedure produces a resumption of micturition a second and a third time, even when considerable pressure has been ineffective. After the third evacuation the reflex is as a rule abolished and can be produced again only after an interval of from one to three minutes. The time between the mechanical stimulation of the abdominal wall and the elimination of the urine is generally, from ten to twenty seconds but occasionally it may be longer. At the beginning of micturition the stimulation of the abdominal walls above the umbilicus seems to be most effective whereas if the bladder is only partly filled stimulation of the abdominal walls below the umbilicus seems to have a better effect. Occasionally the apparently terminated micturition can be resumed by tapping or rubbing lateral portions of the abdominal walls. Observations on several patients extending over three years indicate the uniform course of the reflex. After describing the mechanism of the reflex, the author differentiates it from the visceromotor and from the viscerosensory reflexes and classifies it with a group of reflexes for which he suggests the term cutaneous-visceral reflexes. He is convinced that the therapeutic use of this reflex can prevent for longer periods the accumulation of residual urine and thus make catheterization unnecessary.

Thrombopenic Purpura Following Medication with Iodine—Of eight patients with thrombopenic purpura, observed by Dennig in the course of a year, two had previously received iodine and in a third the iodine metabolism was disturbed by the presence of exophthalmic goiter. The author calls attention to two reports in the literature concerning patients with exophthalmic goiter who developed purpura following iodine therapy. The author does not propound a theory connecting iodine medication with the onset of purpura and considering the rareness of purpura, he does not feel justified in warning against iodine therapy, but he thinks that iodine therapy should be avoided in persons who have had purpura.

Vermiform Appendix in Prodromal Stage of Measles—Schultze relates the clinical history of a girl aged 10, who was subjected to an appendectomy because of symptoms indicating appendicitis. The appendix showed old adhesions and the lymph nodes of the mesenterium were swollen, but there were no signs of acute appendicitis. Histologic examination revealed numerous extremely dark-stained giant cells. He recalled recent reports by Finkeldey and by Fischer showing similar changes in the appendix, when in both instances the appendix had been removed during the prodromal stage of measles. On this basis he diagnosed the case as measles, and he was told that the child had actually developed an exanthem typical for measles. Warthin and Finkeldey have observed similar giant cell formations in the tonsils during the prodromal stage of measles. Since this is the third case in which the giant cells were found in the appendix during the prodromal stage of measles, he thinks that it can be considered typical. The significance of this sign is, however, not fully understood as yet. The author considers two possibilities: the change is a direct result of the unknown virus of measles in which case the tonsils and the appendix could be considered the port of entry of the virus, or the change is due to a reaction of sensitivity. Finkeldey and Fischer incline to the latter assumption. A final decision will not be possible until it is known whether the other lymphatic tissues show similar changes or whether the changes are limited to the tonsils and the appendix. The fact that the same changes occur in the tonsils and in the appendix favors the idea of relationship of these organs.

Scar Formation of Neoplastic Ulcerations Following Local Application of Insulin—Gomes da Costa discusses the increased reactivity of cutaneous neoplasms to roentgen rays after a preliminary local application of insulin and reports the histories of five patients in whom small neoplastic ulcerations on the outside of the nose were healed by the application of an insulin ointment of a concentration of 20 units per gram. In three of the patients the biopsy revealed a basal cell carcinoma and in two a squamous cell epithelioma.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JANUARY-JUNE, 1933

Abstracts of important articles in the following journals have been made in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to Fellows of the American Medical Association for a period not exceeding three days. Two journals may be borrowed at a time. No journals are available prior to 1925. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation, "E," Editorial, "C," Correspondence, "ME," Medical Economics, "ab," abstract, the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 2096

Symposium on Industrial Medicine 1533
Technical Exposition 1536
Treasurer report 1419
Vice President Rudolph Matas address 2021
Woman's Auxiliary 1509
- AMERT** Unsweetened Evaporated Milk 819
- AMIDOPYRINE** See Diabetes Insipidus in fluenza Measles
- AMMONIA** poisoning hoarseness after? 684
urinary 1692—E
- AMMONIUM** Citrate See also Anemia hypochromic
citrate dosage 2040
- AMOXEN** Tablets 1624—B1
- AMPELAIR** 497
- AMPUTATION** effect on blood pressure 1799
- AMYL NITRITE** Inhalation in angina pectoris [Turner] *38
Inhalation in cyanide poisoning [Chen & others] *1920
test for spinal subarachnoid block [Elsberg] 773—ab
- ANAL** See also Anesthesia
poisoning epinephrine and picrotoxin in [Arnett] *1593
sodium in psychoses [Black] 457—ab
sodium in strychnine poisoning [Haggard & Greenberg] 442—C [Kempf & others] *348
- ANACIN** poisoning [Fisher] *730
- ANAFROBIC** Serums See Serum
- ANALAX** Tablets menace 1358—B1
- ANALGESIA** regional spinal [Vebers] 1726—ab
- ANAPHYLAXIS AND ALLERGY** See also
Anaphylaxis
Anaphylaxis and Allergy Eyes tuberculosis Food allergy Gangrene anaphylactic Hay Fever Tuberculosis Urticaria
active substance in shock [Dragstedt] *1
—ab
activity of proteins sterilized by dry heat [Rappaport] 776—ab
after wasp stings [Arntzen] 1378—ab
desensitization in sensitivity to plants 340
erythrocyte increased suspension stability in allergic individuals [Schulhof] *318 (correction) 980
explanation of sensitiveness for the public by George Martyn 1795
gastro intestinal [Haritantis] 1072—ab [Rinkel] 1966—ab
gastro intestinal due to insulin [Williams] *653
local (long continued) skin changes in [Reuterwall] 462—ab
menstrual injecting menstrual extract cures [Harrison] *738
nasal smear cytology and [Johnson] 819—ab
passive latent period in [Lewis] 851—ab
rhinologic aspects [Vaughan] 1,63—ab
sensitivity to asparagus [Halberg] 384—ab
sensitivity to barbituric acid [Jontofsohn] 1214—ab
sensitivity to cat hair 1451
sensitivity to quinine 990
sensitivity to rubber [Obermayer] 1299—ab
sensitization tests fallacies merits [Wald] 374—ab
therapy of disorders [Pinetles] 1999—ab
urticaria 1050

- ANASTOMOSIS** See Duodenum Gallbladder Intestines
ANATOMY building new in Genoa 591
Societa Italiana di anatomia 272
ANCYLOSTOMIA See Hookworm Infestation
ANEMIA See also Anemia Pernicious
achlorhydric [Swift] 377—ab
achlorhydric and allied types gastric secretion in [Harfill] 1897—ab
achylia simplex [Meulengracht] 304—ab
achylous (simple) after stomach surgery [Meulengracht] 1802—ab
acute hemolytic of Lederer [O'Donoghue] 700—ab
after gastric operations [Augban] 781—ab
changes in induced by dye injection [Latta] 79—ab
chronic microcytic [Wright] 1293—ab
classification reclassification [Ottenberg] *1503
etiology mercury poisoning [Dalla Torre] 858—ab
hypochromic primary iron and ammonium citrate copper etc for [Dameshek] *340 (correction) 1360—C
in childhood adult changes in [Feingold] 1807—ab
nervous disorders iron in [Sargant] 856—ab
nutritional and cobalt 579—E
nutritional and metal cages [Garaghty] 1201—ab
of pregnancy See Pregnancy
oysters and [Coulson] 529—ab
secondary aqueous equine liver extract glycerated iron and hemoglobin for [Richter] 697—ab
secondary reduced iron in 591
secondary Thio Albin in 1404
secondary transfusion in [Kochmann] 704—ab
sickle cell in white race [Rosenfeld] 369—ab
sickle cell potassium thiocyanate in [Torrance] 1286—ab
splenic Gaucher's [Potter] 1459—ab
Treatment See also Liver extract
treatment [Ottenberg] *1309
treatment liver extract iron transfusion [Rowland] *537 2040
treatment nuclear extracts from erythrocytes [Pillips] 71—ab
ANEMIA PERNICIOUS Addisonian after gastrectomy [Rowland] 700—ab
age of patients [Holbyll] 1378—ab
blood color index and cell size [Goldhamer] 369—ab
blood picture of after stomach resection [Lottrop] 1566—ab
blood picture of in intestinal atonosis [Seibitzger] 1649—ab
capillary changes in [O'Drain] 837—C
etiological relation to pellagra [Spies] 144—ab
gastric juice in [Heimer] 614—ab
gastric juice nitrogen determinations [Martin] *1475
mental changes in [Piney] 619—ab
metabolism (basal) in [Luzman] 369—ab
of pregnancy See Pregnancy
Treatment See also Liver extract
treatment concentrated gastric juice (1d distal) injection [Morris & others] *171
780—ab (correction) 1000—ab 1286—ab
treatment liver (autolyzed) [Herron & McElroy] *1044
treatment liver extract [McHenry] 1803—ab
treatment liver extract intravenously [Isaacs & others] *629
treatment liver extract orally subcutaneous intramuscularly 1280
treatment parenteral [Seibitzger] 1652—ab
treatment return of hydrochloric acid and ferments after [Davidson] 1728—ab
tuberculosis antagonistic to [Barron] *1390
without anemia [Thijssen] 1378—ab
ANENCEPHALUS diagnosis prenatal [Katsu] 1408—ab
ANESTHESIA See also Analgesia and under Medical Abstracts at end of letter V
airway (nontraumatic pharyngeal) [Cuedel] *1862
A M A sessions on Milwaukee 1527
amylin in obstetrics [Svendsen] 854—ab
amylin in obstetrics penicillin to control restlessness from [Scarcello] 1209—ab
amylin plus tribromethanol in obstetrics 2033
barbiturates with ether by rectum in obstetrics [Lull] 1287—ab
barbituric acid (sodium salt) derivative [Finn] 1074—ab
tribromethanol (avertin) for general surgery [Ransom] 1462—ab
tribromethanol in lung edema [Koonitz] 1465—ab
tribromethanol in operation on Henry Ford for hernia 443
carbon dioxide toxicity *19 (reply) [Lundy] 842 (Waters) 127—C
chloroform and ether distilling by colored bulb 1552
diethane new local [Rider] 1884—ab
diviny oxide [Gelfan] 146—ab [Leake] 1463—ab
effect on remedies to control circulation 2031
ether commensurate discovery Crawford W Long Day 1437
ANESTHESIA—Continued
ether convulsions (late) [Sears] *1150
[Waldbott] 1547—C
ether or nitrous oxide effect on syphilis serodiagnostic tests 891
ethyl chloride 1199
explosion 2031
fatalities increased number South Africa 204
infiltration in obstetrics [Greenhill] 1643—ab
liver glycogen and [Murphy] 534—ab
local curiement under 135
local lip injury during tooth extraction 1362 1789
local of brachial plexus 279
mask sterilized in compound cresol solution burns from [Herwick & Treweek] *407
nupercaline in rhinolaryngology [Gatewood] 852—ab
nupercaline spinal [Johnson] 1070—ab
nupercaline toxicity 301
of phrenic nerve as test operation [Hein] 703—ab
paraaldehyde as basal anesthetic [Thompson] 701—ab
paraaldehyde by rectum evening before operation [Stewart] 1139—ab
preanesthetic values of amylal penicillin barbitol phenobarbital barbitol [Swanson] 1085—ab
scopolamine amnesia in labor [Macafee] 998—ab
skin variations in trigeminal neuralgia [Wilkins] 1641—ab
spinal in children [Junkin] 1462—ab
spinal myelitis after 1361
spinal routine [Walters] 1070—ab
spinal acetate inflammation from 687
spinal technique [Bower & others] *245
ANFURYSM aortic (descending thoracic) thoracic pulsation in 1445
aortic dissecting diagnosed during life [Kellogg & Head] *1157
arteriorenous effect on circulation [Fitch] 1074—ab
at base of brain [Harbitt] 1734—ab
femoral in tuberculous mesarteritis [Baumgarten & Cantor] *1919
of left ventricle [Fogel] *39
ANGINA agranulocytic adenine sulphate in [Reznikoff] 1724—ab
agranulocytic liver extract for [Foran & others] *1917
Vincent's arsenic poisoning from mouthwash [Lewenberg & Nalae] *737
ANGINA PECTORIS blood pressure during attacks [Levine] 1805—ab
diagnosis by electrocardiogram [Scherf] 1977—ab
diaphragmatics [Hofbauer] 1921—ab
electrocardiogram during attack [Turner] *39
fatal [Fitzhugh & Hamilton] *475
pain in [Dietrich] 1073—ab
treatment magnesium [Bandmann] 1977—ab
ANGIOMA cavernous of spleen spontaneous rupture [Haines & McElroy] *1862
Goldstein's hereditary familial bleeding (non purpura and nonhemophilic) 1491
of skeletal muscles [Jenkin] 75—ab
ANHYDREMIA See Blood water content
ANIMAL EXPERIMENTATION 1414
attempt to void vivisection law Illinois 49
medicine and experimental laboratory 700—E
ANIMALS See also Cats Cows Rabbits
Squirrels etc
nutrition cobalt in [Starck] 1291—ab
ANKLEFS edema chronic 819
periodic swelling 62
ANKYLOSIS acetylcholine for [Fischer] 1729—ab
ANCYLOSTOMIASIS See Hookworm Infestation
ANOMALIES See Spine Tendons
ANOREXIA See Appetite
ANOXEMIA See Blood oxygen
ANTHELMINTIC See Tapeworm Infestation
ANTHRAX stimulated by venomous stings [Gougout] 1071—ab
ANTHIPOLOXY and skin nerve [Sambarger] 854—ab
ANTIADENTIS 1974—BI
ANTIBODY Reaction See Claudium Fever
ANTIDIURIC See Diabetes Insipidus Treatment
ANTIDOTES See Antidote Strychnine
ANTICEN See also Bacterium Brucella abortus Pallida Antigen Reaction Pollen Tuberculosis
Bordet's nonspecific fixability of guinea pig serum [Lustig] 1207—ab
ANTIMONY and potassium tartrate chlor butanol as preservative to 604
poisoning from cheap enamel ware 1189
ANTISEPTICS See also Ceroalactic Cunn
Antiseptic Repellent Antiseptic V Cris standardization A M A Council on Pharmacy and Chemistry on 1403
troches 2079
ANTITOXIN See Diphtheria Gangrene Scarlet Fever Tetanus
ANTIVIRUSES specific [Hearedka] *76—ab
ANTONELLI Test See Gallbladder roentgen study
ANTROM OF HIGHMORE See Maxillary Sinus
ANTS hospital invaded by Berlin 1446
ANTLITRIN—S See Sex hormones
ANUS bleeding from [Drueck] 293—ab
Fistula See Fistula
mucosa prolapse in children 354
AORTA abdominal aortography 1555
Aneurysm See Aneurysm
calcification in hypervitaminosis D [Ham] 613—ab
coarctation [Shapiro] *640
rupture spontaneous [Arenberg] 1003—ab
AORTIC VALVE Duroziez's sign [Blumgart & Ernestene] *173 (correction) 434
AOIAMA TANEMUCHI memorial ceremony 985
APHASIA described by Holmes [Hagemann] 1713—C
APHRODISIAC saltpeter as anaphrodisiac 361
APHRODITE 276—BI
APICULOSIS See Tuberculosis Pulmonary
APOMORPHINE See Strychnine poisoning
APOPLEXY See Brain hemorrhage Supra renals hemorrhage
APPARATUS See also Air filter Diathermy Electric Instruments Oxygen tent Re spirator Splints Sunlamps Ultraviolet Rays etc
accidental injuries in office practice [Kovacs] *107
airway (nontraumatic pharyngeal) [Cuedel] *1862
animal roentgenographic table [Moore & others] *711
